Abstract

The Michaelis–Menten kinetics and the reverse Michaelis–Menten kinetics are two popular mathematical formulations used in many land biogeochemical models to describe how microbes and plants would respond to changes in substrate abundance.

- ⁵ However, the criteria of when to use which of the two are often ambiguous. Here I show that these two kinetics are special approximations to the Equilibrium Chemistry Approximation kinetics, which is the first order approximation to the quadratic kinetics that solves the equation of enzyme-substrate complex exactly for a single enzyme single substrate biogeochemical reaction with the law of mass action and the assump-
- tion of quasi-steady-state for the enzyme-substrate complex and that the product genesis from enzyme-substrate complex is much slower than the equilibration between enzyme-substrate complexes, substrates and enzymes. In particular, I showed that the derivation of the Michaelis–Menten kinetics does not consider the mass balance constraint of the substrate, and the reverse Michaelis–Menten kinetics does not con-
- sider the mass balance constraint of the enzyme, whereas both of these constraints are taken into account in the Equilibrium Chemistry Approximation kinetics. By benchmarking against predictions from the quadratic kinetics for a wide range of substrate and enzyme concentrations, the Michaelis–Menten kinetics was found to persistently under-predict the normalized sensitivity $\partial \ln v / \partial \ln k_2^+$ of the reaction velocity v with
- ²⁰ respect to the maximum product genesis rate k_2^+ , persistently over-predict the normalized sensitivity $\partial \ln v / \partial \ln k_1^+$ of v with respect to the intrinsic substrate affinity k_1^+ , persistently over-predict the normalized sensitivity $\partial \ln v / \partial \ln[E]_T$ of v with respect the total enzyme concentration $[E]_T$ and persistently under-predict the normalized sensitivity $\partial \ln v / \partial \ln[S]_T$ of v with respect to the total substrate concentration $[S]_T$. Mean-
- ²⁵ while, the reverse Michaelis–Menten kinetics persistently under-predicts $\partial \ln v / \partial \ln k_2^+$ and $\partial \ln v / \partial \ln [E]_T$, and persistently over-predicts $\partial \ln v / \partial \ln k_1^+$ and $\partial \ln v / \partial \ln [S]_T$. In contrast, the Equilibrium Chemistry Approximation kinetics always gives consistent predictions of $\partial \ln v / \partial \ln k_2^+$, $\partial \ln v / \partial \ln k_1^+$, $\partial \ln v / \partial \ln [E]_T$ and $\partial \ln v / \partial \ln [S]_T$. Since the

Equilibrium Chemistry Approximation kinetics includes the advantages from both the Michaelis–Menten kinetics and the reverse Michaelis–Menten kinetics and it is applicable for almost the whole range of substrate and enzyme abundances, soil biogeochemical modelers therefore no longer need to choose when to use the Michaelis–Menten kinetics or the reverse Michaelis–Menten kinetics. I expect removing this choice ambiguity will make it easier to formulate more robust and consistent land biogeochemical models.

1 Introduction

- The recent recognition that the typical turnover pool based soil carbon models cannot
 model the priming effect has revived the interest in developing microbe explicit soil biogeochemistry models. This has been manifested in a long list of microbial models that were published in the last few years (e.g., Schimel and Weintrub, 2003; Moorhead and Sinsabaugh, 2006; Allison et al., 2010; German et al., 2012; Wang et al., 2013; Wieder et al., 2013; He et al., 2014; Riley et al., 2014; Xenakis and Williams, 2014; Tang and
 Riley, 2015; Sulman et al., 2015; Wieder et al., 2015). To build a microbial model, the substrate kinetics is fundamental as it describes the rate that microbes would uptake a substrate and represents the first step towards describing how microbes would decompose the soil organic matter. Among the many mathematical formulations of substrate kinetics (see Tang and Riley, 2013 for a review), the Michaelis–Menten (MM)
 kinetics is used mostly, because it succeeded in many applications ever since its birth
- in the early 20 century (Michaelis and Menten, 1913). However, Schimel and Weintraub (2003) noticed in their study that the MM kinetics led to undesirable instability in their model of microbial soil carbon decomposition and suggested that the decomposition rate varies more like an asymptotic function of enzyme such that the Reverse
- ²⁵ Michaelis–Menten (RMM) kinetics would better model the soil carbon decomposition dynamics. The success by Schimel and Weintraub has led to a number of studies to use the RMM kinetics as the backbone of their microbial models, including Moorhead

and Sinsabaugh (2006)'s model of litter decomposition, Drake et al. (2013)'s model for root priming, Waring et al. (2013)'s model for change in microbial community structure in soil carbon and nitrogen cycling, and Averill (2014)'s model for change in microbial allocation in soil carbon decomposition.

- ⁵ Wang and Post (2013) pointed out that both the MM kinetics and the RMM kinetics are special approximations to the quadratic kinetics that exactly solves for the enzyme-substrate complex under the quasi-steady-state approximation (QSSA), which states that the enzyme-substrate complexes are in instantaneous equilibrium with enzyme and substrate concentrations (Borghans et al., 1996). They further concluded that the MM kinetics is applicable when the substrate concentration for excende the
- that the MM kinetics is applicable when the substrate concentration far exceeds the enzyme concentration, and the RMM kinetics is applicable when either the enzyme concentration far exceeds the substrate concentration or vice versa. The condition for the MM kinetics to be applicable as provided by Wang and Post (2013) was however much narrower than that was proposed in some earlier studies. For instance, Borghans
- et al. (1996) showed that the MM kinetics is a good approximation to the quadratic kinetics when the enzyme concentration is far smaller than the sum of the substrate concentration and the Michaelis–Menten constant (Palsson, 1987; Segel, 1988; Segel and Slemrod, 1989). To handle enzyme-substrate interactions under high enzyme concentrations, Borghans et al. (1996) proposed the total quasi-steady-state approximation
- (tQSSA) and obtained a substrate kinetics that was a special case of the later proposed Equilibrium Chemistry Approximation kinetics by Tang and Riley (2013). Tang and Riley (2013) applied the law of mass action with tQSSA and derived the ECA kinetics to describe the formation of enzyme-substrate complexes in a network of an arbitrary number of enzymes and substrates.
- ²⁵ The consistent application of mathematical formulations to describe a dynamic system is critical for the model to successfully resolve the empirical measurements that observe the dynamic system. This consistency requirement has been raised in several studies using microbe explicit models. For instance, Maggi and Riley (2009) have found the MM kinetics has to be revised to resolve the evolution of δ^{15} N-N₂O in their

data of nitrification and denitrification. Druhan et al. (2012) later used Maggi and Riley (2009)'s revision to obtain an improved modeling of the δ^{34} S data collected in the acetate-enabled uranium bioremediation at the US Department of Energy's Rifle Integrated Field Research Challenge site. Tang and Riley (2013) showed that the MM kinetics failed to resolve the evolution of lignocellulose index during a litter decompo-

- sition experiment. I was not able to find any example of using the RMM kinetics to model the kinetic isotope fractionation. However, because the RMM kinetics is a linear function of the substrate concentration, its application for modeling kinetic isotope fractionation will be doomed inevitably. Therefore, a substrate kinetics that merges the advantages from both the MM kinetics and the RMM kinetics would be a better choice
 - for developing robust microbial models.

The call for a substrate kinetics that can consistently work across a wide range of substrate and enzyme (or more broadly competitor) concentrations becomes more imperative when the land biogeochemical models are required to resolve plant-microbe

- interactions. In plant-microbe interactions, both substrates and competitors evolve constantly and their concentration ratios could vary orders of magnitudes. For instance, when a soil is seriously nitrogen limited, the aqueous nitrogen concentration is much lower than the volumetric density of competitors and substrate dynamics may follow more closely to the MM kinetics. However when a large dose of fertilizer is added, the
- soil quickly becomes nitrogen saturated, such that the dynamics would follow more closely to the variation of competitors (or enzymes) as represented in the RMM kinetics. To consistently model the soil nitrogen dynamics that fluctuates between status of nitrogen limitation and nitrogen saturation, one therefore has to constantly choose between the MM kinetics and RMM kinetics, making a consistent mathematical formu-
- ²⁵ lation theoretically impossible. Therefore, an approach that includes the advantages from both the MM kinetics and RMM kinetics will significantly advance our capability in modeling soil biogeochemical processes. Fortunately, such kinetics (aka the ECA kinetics) was already derived in Tang and Riley (2013), but my coauthor and I did not give a theoretical analysis for the relationships between MM kinetics, RMM kinetics

and the ECA kinetics, nor did we explain how the parametric sensitivity would vary depending on the choice of substrate kinetics and whether the ECA kinetics is superior across the whole range of feasible kinetic parameters. Such an analysis will also help reveal the pitfalls that may exist in biogeochemical models that rely on the use of MM kinetics (Allison et al., 2010) or RMM kinetics (e.g. Averill, 2014) or the combination of

the two (e.g. Sihi et al., 2010) of Hinn kinetics (e.g. Avenil, 2014) of the combination of the two (e.g. Sihi et al., 2015), when the model is otherwise compared to its equilibrium chemistry based formulation that solves the biogeochemical system exactly under the tQSSA (readers please refer to Tang and Riley (2013) for a thorough discussion on why the equilibrium chemistry formulation should be the benchmark for models based
 on MM kinetics, RMM kinetics and ECA kinetics).

In the this study, I first review how the ECA kinetics could be derived from the quadratic kinetics and how the MM kinetics and the RMM kinetics could be derived from the ECA kinetics or directly from the equilibrium chemistry formulation of the enzymesubstrate interaction. Then I analyze how accurate the MM kinetics, the RMM kinetics and the ECA kinetics could approximate the parametric sensitivity, as one would derive from the quadratic kinetics that is exact for the one enzyme and one substrate biogeo-

chemical reaction. Based on these analyses, I finally give recommendations on how to obtain more robust microbial models for soil biogeochemical modeling.

2 The Mathematical relationship between different kinetics

Below I first review how one could obtain the quadratic kinetics under the QSSA for a biogeochemical reaction that involves one enzyme and one substrate. Then I show how one could derive the ECA kinetics, the MM kinetics and the RMM kinetics. The biogeochemical reaction of the system is

$$E + S \underset{k_{1}^{-}}{\overset{k_{1}^{+}}{\Leftrightarrow}} ES \xrightarrow{k_{2}^{+}} E + P$$

(1)

where *E*, *S*, *ES* and *P* are, respectively, enzyme, substrate, enzyme-substrate complex and product. The three kinetic parameters are intrinsic substrate affinity k_1^+ (m³mol⁻¹s⁻¹), backward enzyme-substrate dissociation constant k_1^- (s⁻¹) and product genesis rate k_2^+ (s⁻¹).

By the law of mass action, the governing equations for biogeochemical reaction (1) are

$$\frac{d[E]}{dt} = -k_1^+[S][E] + (k_1^- + k_2^+)[ES]$$
(2)

$$\frac{d[S]}{dt} = -k_1^+[S][E] + k_1^-[ES]$$
(3)

$$\frac{d[ES]}{dt} = k_1^+[S][E] - (k_1^- + k_2^+)[ES],$$
(4)
$$\frac{d[P]}{dt} = k_2^+[ES]$$
(5)

10

5

Here and below, I use [.] to designate the concentration (mol m^{-3}) of a given state variable.

Under the QSSA, Eq. (4) is approixmated as

 $[S][E] = K_{ES}[ES]$

¹⁵ where $K_{ES} = (k_1^- + k_2^+) / k_1^+$ (mol m⁻³) is the Michaelis–Menten constant. For a small temporal window when the amount of the product is negligible, it holds that $[P] \ll [ES] + [S] = [S]_T$, then [ES] could be solved from Eq. (6) under the constraints

 $[ES] + [E] = [E]_T$

²⁰ $[ES] + [S] = [S]_T$

(6)

(7)

(8)

Equations (6)–(8) can be recast into the following quadratic equation

$$[ES]^{2} - (K_{ES} + [E]_{T} + [S]_{T})[ES] + [E]_{T}[S]_{T} = 0$$
(9)

By taking the physically meaningful solution to Eq. (9) one obtains the quadratic kinetics formulation of [ES]

$${}_{5} \quad [ES] = \frac{(K_{ES} + [E]_{T} + [S]_{T})}{2} \left(1 - \sqrt{1 - \frac{4[E]_{T}[S]_{T}}{(K_{ES} + [E]_{T} + [S]_{T})^{2}}} \right)$$
(10)

2.1 The Equilibrium Chemistry Approximation kinetics

To obtain the ECA formulation of the enzyme-substrate complex, one assumes

$$\varepsilon = \frac{[E]_T[S]_T}{(K_{ES} + [E]_T + [S]_T)^2} \ll 1$$
(11)

Then when the Taylor expansion of Eq. (10) is truncated to the first order of ε , the ECA formulation of [*ES*] is obtained

$$[ES] = \frac{[E]_{T}[S]_{T}}{K_{ES} + [E]_{T} + [S]_{T}}$$
(12)

The application of Eq. (12) implies

 $\frac{\mathsf{d}[S]_T}{\mathsf{d}t} = -k_2^+[ES]$

which together with the QSSA forms the tQSSA (Borghans et al., 1996).

(13)

2.2 The Michaelis–Menten kinetics

The MM kinetics can be derived in two different approaches. In the first approach, by assuming $K_{ES} + [S]_T \gg [E]_T$, Eq. (12) gives the MM formulation of [ES]

$$[ES] \approx \frac{[E]_T[S]_T}{K_{ES} + [S]_T}$$

10

15

⁵ In the second approach, one solves [ES] from Eqs. (6) and (7) and obtains

$$[ES] = \frac{[E]_{T}[S]}{K_{ES} + [S]}$$

Note $[S] = [S]_T - [ES] < [S]_T$, and because [ES] is a monotonically increasing function of [S], [ES] computed from Eq. (14) will be greater than that from Eq. (15). However, almost all existing applications do not differentiate between Eqs. (14) and (15). The strict application of Eq. (14) implies the evolution of substrate is computed by Eq. (13), whereas under the QSSA the strict application of Eq. (15) implies

 $\frac{\mathrm{d}[S]}{\mathrm{d}t} = -k_2^+[ES]$

When [S] is low, or when enzyme concentration $[E]_T$ is high, equating [S] to $[S]_T$ and ignoring the contribution of $[E]_T$ in calculating the enzyme-substrate complex [ES] will cause significant error in computing the parametric sensitivities as I will show in Sect. 3.

The sufficient condition $K_{ES} + [S]_T \gg [E]_T$ (which always leads to $\varepsilon \ll 1$, the sufficient condition to derive the ECA kinetics) for the MM kinetics to be applicable was well recognized in early studies; however, it was often misinterpreted as $[S]_T \gg [E]_T$ (see a discussion in Borghans et al., 1996). Yet, more importantly, I note that the derivation

of the MM kinetics does not take into account the mass balance constraint for substrate (Eq. 8). As I will show in Sect. 3, the negligence of mass balance constraint for substrate will lead to poor predictions of parametric sensitivity by the MM kinetics when benchmarked with the quadratic kinetics.

(14)

(15)

(16)

2.3 The reverse Michaelis–Menten kinetics

There are also two approaches to derive the RMM kinetics. In the first approach, one assumes $K_{ES} + [E]_T \gg [S]_T$, then from Eq. (12), obtains the RMM formulation of [ES]

$$[ES] \approx \frac{[E]_T[S]_T}{K_{ES} + [E]_T}$$

⁵ In the second approach, one solves [ES] from Eqs. (6) and (8)

$$[ES] = \frac{[E][S]_{T}}{K_{ES} + [E]}$$
(18)

Note $[E] = [E]_T - [ES] < [E]_T$, and because [ES] is a monotonically increasing function of [E], [ES] calculated from Eq. (17) will be greater than that from Eq. (18). Like the MM kinetics, existing applications have treated Eqs. (17) and (18) as equivalent.

¹⁰ Here the condition $K_{ES} + [E]_T \gg [S]_T$ (which always leads to $\varepsilon \ll 1$, the sufficient condition to derive the ECA kinetics) for the RMM kinetics to hold is more general than the condition $[E]_T \gg [S]_T$ proposed in Wang and Post (2013). I also note that the derivation of the RMM kinetics does not take into account the mass balance constraint for enzyme (Eq. 7). This negligence of the mass balance constraint for enzyme will lead the RMM kinetics to predict poor parametric sensitivities when benchmarked with the quadratic kinetics.

3 Parametric sensitivity analyses

20

I below analyze the sensitivities of the reaction velocity with respect to the four parameters as predicted by the four kinetics. The four parameters are (1) maximum product genesis rate k_2^+ , (2) intrinsic substrate affinity k_1^+ , (3) the total enzyme concentration $[E]_T$ and (4) the total substrate concentration $[S]_T$. The reaction velocities predicted by

(17)

the four different kinetics are, respectively

$$v_{\rm QD} = \frac{k_2^+ (K_{ES} + [E]_T + [S]_T)}{2} \left(1 - \sqrt{1 - \frac{4[E]_T [S]_T}{(K_{ES} + [E]_T + [S]_T)^2}} \right)$$

for the quadratic kinetics,

$$v_{\text{ECA}} = \frac{k_2^+[E]_T[S]_T}{K_{ES} + [E]_T + [S]_T}$$

5 for the ECA kinetics,

$$v_{\rm MM} = \frac{k_2^+[E]_T[S]_T}{K_{ES} + [S]_T}$$

for the MM kinetics, and

$$v_{\text{RMM}} = \frac{k_2^+[E]_T[S]_T}{K_{ES} + [E]_T}$$

for the RMM kinetics.

¹⁰ In evaluating the parametric sensitivity, I made the conventional assumption that $k_1^- \ll k_2^+$ to obtain a better presentation of the results (although excluding this assumption will not change the conclusion below). This assumption leads to $K_{ES} = k_2^+/k_1^+$, which states that the apparent substrate affinity $1/K_{ES}$ is a linearly decreasing function of k_2^+ , a relationship that has been used to characterize the K-r tradeoff (e.g. Litchman te al., 2008). Because K_{ES} is a function of k_2^+ , the intrinsic affinity k_1^+ better describes the substrate affinity for the enzymes.

In addition, to simplify the presentation, I define $y = K_{ES} + [E]_T + [S]_T$ and $x = 4[E]_T[S]_T/y^2$. Since the derivations for the MM and RMM kinetics related parametric sensitivities could be derived from the ECA predictions straightforwardly, I only provide

(19)
$$\operatorname{Paper}_{k_{1}}^{\operatorname{GMDD}}$$

(20) $\operatorname{Paper}_{k_{1}}^{\operatorname{Call}}$ $\operatorname{Paper}_{k_{1}}^{\operatorname{Call}}^{\operatorname{Call}}$ $\operatorname{Paper}_{k_{1}}^{\operatorname{Call}}^{\operatorname{Call}}^{\operatorname{Call}}^{\operatorname{C$

details to derive the results for the quadratic and ECA related parametric sensitivities (Appendices A and B). Nevertheless, to help the readers to visualize the differences in the predicted parametric sensitivities by using different kinetics, I have summarized the comparison in four different figures: Fig. 1 for k_2^+ , Fig. 2 for k_1^+ , Fig. 3 for $[E]_T$, and Fig. 4 for $[S]_T$. All sensitivities are evaluated over the 2-D normalized substrate-enzyme concentration domain $[0.001, 1000] \times [0.001, 1000]$, with both $[E]_T$ and $[S]_T$ normalized by K_{ES} . In addition, because the quadratic kinetics is exact under the QSSA, its predictions are used to benchmark the predictions made by the ECA kinetics, MM kinetics and RMM kinetics (see d panels in the figures). For comparison between predictions by the ECA kinetics and the quadratic kinetics, I plotted the normalized sensitivities as 2-D functions of the normalized substrate $[S]_T/K_{ES}$ and $[E]_T/K_{ES}$ (see a and b panels in the figures), and evaluated their differences using the index $(a_{\text{QD}} - a_{\text{ECA}}) / (a_{\text{QD}} + a_{\text{ECA}})$ (see c panels in the figures), where the subscripts QD and ECA kinetics.

15 the ECA kinetics.

3.1 Reaction velocity vs. k_2^+

The normalized sensitivity of the reaction velocity vs. k_2^+ are, respectively,

$$\frac{k_2^+}{v_{\rm QD}}\frac{\partial v_{\rm QD}}{\partial k_2^+} = 1 + \frac{K_{ES}}{y} - \frac{K_{ES}}{y} \left(1 - \sqrt{1 - x}\right)^{-1} (1 - x)^{-1/2} x$$
(23)

7674

for the quadratic kinetics,

$${}_{20} \quad \frac{k_2^+}{v_{\text{ECA}}} \frac{\partial v_{\text{ECA}}}{\partial k_2^+} = 1 - \frac{K_{ES}}{K_{ES} + [E]_T + [S]}$$

for the ECA kinetics,

$$\frac{k_2^+}{v_{\rm MM}}\frac{\partial v_{\rm MM}}{\partial k_2^+} = 1 - \frac{K_{ES}}{K_{ES} + [S]_T}$$

(24)

(25)

for the MM kinetics, and

$$\frac{k_2^+}{v_{\text{RMM}}} \frac{\partial v_{\text{RMM}}}{\partial k_2^+} = 1 - \frac{K_{ES}}{K_{ES} + [E]_T}$$

for the RMM kinetics.

From above, it is observed that both the MM kinetics and the RMM kinetics predict
a less variable and lower parametric sensitivity than does the ECA kinetics, because the ECA kinetics predicts a more variable and larger denominator in the second term (in Eq. 24) as compared to that by the MM kinetics (Eq. 25) and the RMM kinetics (Eq. 26). Large deviations between predictions by the MM kinetics and the ECA kinetics are expected at high enzyme concentrations; whereas large deviations between predictions by the RMM kinetics are expected at high substrate concentrations. Predictions by the MM kinetics and RMM kinetics are also smaller than that by the quadratic kinetics (green diamonds and black stars in Fig. 1d). In contrast, the ECA kinetics consistently captures the variability of the normalized sensitivity, with some over-estimation (no greater than 5%) under moderate enzyme and substrate (Fig. 1a).

3.2 Reaction velocity vs. k_1^+

The normalized sensitivity of the reaction velocity vs. k_1^+ are, respectively,

$$\frac{k_1^+}{v_{\rm QD}}\frac{\partial v_{\rm QD}}{\partial k_1^+} = -\frac{K_{ES}}{y} + \frac{K_{ES}}{y}(1-x)^{-1/2}\left(1-\sqrt{1-x}\right)^{-1}x$$

7675

20 for the quadratic kinetics,

$$\frac{k_1^+}{v_{\text{ECA}}} \frac{\partial v_{\text{ECA}}}{\partial k_1^+} = \frac{K_{ES}}{K_{ES} + [E]_T + [S]_T}$$

Discussion Paper GMDD 8,7663-7691,2015 **Relationships** between substrate kinetics **Discussion** Paper J. Y. (27)

(28)

for the ECA kinetics,

$$\frac{k_1^+}{v_{\rm MM}}\frac{\partial v_{\rm MM}}{\partial k_1^+} = \frac{K_{ES}}{K_{ES} + [S]_T}$$

for the MM kinetics, and

$$\frac{k_1^+}{v_{\text{RMM}}}\frac{\partial v_{\text{RMM}}}{\partial k_1^+} = \frac{K_{ES}}{K_{ES} + [E]_7}$$

₅ for the RMM kinetics.

10

15

From Eqs. (28)–(30), it is inferred that both the MM kinetics and the RMM kinetics predict a less variable and higher normalized sensitivity with respect to k_1^+ than does the ECA kinetics. Large difference between predictions by the ECA kinetics and the MM kinetics are expected at high enzyme concentrations; whereas large difference between predictions by the ECA kinetics and the RMM kinetics are expected at high substrate concentrations. The predictions by the MM kinetics and the RMM kinetics are also lower than that by the quadratic kinetics (Fig. 2d), whereas the ECA kinetics predicts consistent parametric sensitivity for the wide range of enzyme and substrate concentrations (Fig. 2). The under-prediction by the ECA kinetics is significant only at high substrate and high enzyme concentrations (Fig. 2c), where the parametric sensitivity is close to zero (Fig. 2a and b).

3.3 Reaction velocity vs. $[E]_T$

The normalized sensitivity of the reaction velocity vs. $[E]_T$ are, respectively,

$$\frac{[E]_T}{v_{\rm QD}} \frac{\partial v_{\rm QD}}{\partial [E]_T} = \frac{[E]_T}{y} + \frac{[E]_T}{y} \left(1 - \sqrt{1 - x}\right)^{-1} (1 - x)^{-1/2} \times \left(\frac{2[S]_T}{y} - x\right)$$
(31)

20 for the quadratic kinetics

$$\frac{[E]_T}{v_{\text{ECA}}} \frac{\partial v_{\text{ECA}}}{\partial [E]_T} = 1 - \frac{[E]_T}{K_{ES} + [E]_T + [S]_T}$$

10

20

From above, it is observed that the MM kinetics predicts a constant normlzied sensivity of the reaction vecloity with respect to the total enzyme concentrion $[E]_T$. The RMM kinetics predicts the normalized sensitivity as a monotonically decreasing function of the normalized enzyme concentration $[E]_T/K_{ES}$. The prediction by the ECA kinetics is a function of both the normalized substrate concentration $[S]_T/K_{ES}$ and the normalized enzyme concentration $[E]_T/K_{ES}$. Compared to predictions by the quadratic kinetics, the MM kinetics persistently over-estimates the parametric sensitivity (green diamonds in Fig. 3d), whereas the RMM kinetics persistently under-estimates the parametric sensi-

tivity (black stars in Fig. 3d). The ECA predictions are largely consistent with that by the quadratic kinetics (Fig. 3), albeit with some significant deviations in the regions of very high substrate and enzyme concentrations (Fig. 3c), where the parametric uncertainty is moderate or low (Fig. 3a and b).

3.4 Reaction velocity vs. $[S]_T$

The normalized sensitivity of the reaction velocity vs. $[S]_T$ are, respectively,

$$\frac{[S]_T}{v_{\rm QD}}\frac{\partial v_{\rm QD}}{\partial [S]_T} = \frac{[S]_T}{y} + \frac{[S]_T}{y} \left(1 - \sqrt{1 - x}\right)^{-1} (1 - x)^{-1/2} \times \left(\frac{2[E]_T}{y} - x\right)$$
(35)

for the qudratic kinetics

$$\frac{[S]_T}{v_{\text{ECA}}} \frac{\partial v_{\text{ECA}}}{\partial [S]_T} = 1 - \frac{[S]_T}{K_{ES} + [E]_T + [S]_T}$$

(34)

(36)

for the ECA kinetics,

$$\frac{[S]_{T}}{v_{\text{MM}}} \frac{\partial v_{\text{MM}}}{\partial [S]_{T}} = 1 - \frac{[S]_{T}}{K_{ES} + [S]_{T}}$$

for the MM kinetics, and

 $\frac{[S]_{T}}{v_{\mathsf{RMM}}}\frac{\partial v_{\mathsf{RMM}}}{\partial [S]_{T}} = 1$

5 for the RMM kinetics.

Because $[S]_T$ and $[E]_T$ are symmetric in the quadratic kinetics and the ECA kinetics, the predicted normalized sensitivity of the reaction velocity with respect to the total substrate concentration $[S]_T$ mirrors that of $[E]_T$ along the lower left to upper right diagonal (Fig. 3 vs. 4). Such symmetric relationships also exist in predictions by the MM kinetics and the RMM kinetics, however, the MM kinetics persistently under-predicts the normalized sensitivity of the reaction velocity with respect to $[S]_T$, and the RMM kinetics predicts a constant sensitivity (Eq. 38). The ECA kinetics once again predicts consistent parametric sensitivity when compared with the quadratic kinetics.

4 Discussions and conclusions

¹⁵ From the above analyses, I showed that the ECA kinetics is a better approximation to the quadratic kinetics, which, obtained from the law of mass action and the quasi-stead-state approximation, is the exact solution to the governing equation of substrate-enzyme interaction. In contrast, the Michaelis–Menten kinetics and the reverse Michaelis–Menten kinetics are inferior in approximating the quadratic kinetics over the wide range of enzyme and substrate concentrations. The worse performances of the MM kinetics than the ECA kinetics in approximating the quadratic kinetics stems

(37)

(38)

from the negligence of the mass balance constraint of the substrate during the derivation of the MM kinetics; while the worse performance of the RMM kinetics in approximating the quadratic kinetics is caused by the negligence of the mass balance constraint of the enzyme during the derivation of the RMM kinetics. The failure to simulta-

- neously consider the mass balance constraints for both enzyme and substrate during their derivation caused the MM kinetics and the RMM kinetics to predict significantly biased normalized sensitivity of the reaction velocity with respect to the two kinetic parameters k₁⁺ and k₂⁺, the total enzyme concentration [*E*]₇ and the total substrate concentration [*S*]₇. Although being a first order approximation to the quadratic kinetics inder the assumption that [*E*]₇[*S*]₇ ≪ (K_{ES} + [*E*]₇ + [*S*]₇)², the ECA kinetics predicts consistent parametric sensitivity with that by the quadratic kinetics over the wide range.
- consistent parametric sensitivity with that by the quadratic kinetics over the wide range of normalized substrate and enzyme concentrations.

In modeling the complex soil biogeohcmeical dynamics, the consistency between the used kinetics and the equilibrium chemistry formulation of the relationships between anyway, substrates and anyway substrates complexes might be very critical (Tang

- enzymes, substrates and enzyme-substrate complexes might be very critical (Tang and Riley, 2013), but it has been unfortunately under-appreciated in many previous studies. In Tang and Riley (2013), it was shown that for a system involving three microbes competitively decompose three carbon substrates, the MM kinetics failed wildly even with industrious calibration (see their Fig. 12). In an earlier study, Moorhead and
- Sinsabaugh (2006) have to prescribe the relative decomposition between lignin and cellulose in order to resolve the lignocellulose index dynamics. The ECA kinetics was able to consistently resolve the lignin-cellulose dynamics during the litter decomposition by that it explicitly considers the mass balance constraints for both the substrates and enzymes (or, effectively, abundance of competitors; Tang and Riley, 2013).
- ²⁵ If the ecological dynamics involved in microbial processing of various substrates does approximately obey the law of mass action and the total-quasi-steady-state approximation (as it is already implied in any microbe explicit model that uses the MM kinetics or the RMM kinetics), then the analytically tractable ECA kinetics is a much more powerful and mathematically more consistent tool than the popular MM kinetics

and RMM kinetics that are currently used in many microbial models. Indeed, a recent application (Zhu and Riley, 2015) indicated that by representing plant-microbe competition of soil mineral nitrogen using the ECA kinetics, the predicted global nitrogen dynamics became much more consistent with that inferred from the δ^{15} N isotopic data

- ⁵ (Houlton et al., 2015). The ECA kinetics was also found to satisfyingly model the plantmicrobe competitions for phosphorus and mineral nitrogen at several fertilized sites (Zhu et al., 2015) and predicted consistent vertical nitrogen uptake profile measured at an alpine meadow ecosystem (Zhu et al., 2015). Theoretically, because either the MM kinetics or the RMM kinetics works only in a small subdomain of the parameters that
- are used in the original quadratic kinetics, models based on MM kinetics or RMM kinetics may likely have much lower predictive capability than that is implied in the mechanisms that the models are trying to represent (e.g. the law of mass action, which is the foundation to all substrate kinetics). I therefore recommend modelers to use the ECA kinetics to describe the substrate uptake processes in modeling microbe regulated bio-
- geochemical processes, because, with the same number of parameters as that would be used in either the MM kinetics or the RMM kinetics, the ECA kinetics achieved better accuracy in approximating the exact quadratic kinetics for a biogeochemical reaction that involves a single enzyme and a single substrate, and also for systems that involve many substrates and many enzymes (Tang and Riley, 2013), where the latter are much
- ²⁰ more common in the natural environment that we are trying to model. Last and more importantly, the ECA kinetics could save the modelers from the pain of deciding when to use the MM kinetics or the RMM kinetics to represent a soil that fluctuates between status of nutrient limitation and nutrient saturation, for which neither the MM kinetics nor the RMM kinetics is (but ECA is) theoretically consistent with the law of mass action, it is the transformed of tr
- $_{\mbox{\tiny 25}}$ the best theory we have for modeling macroscale biogeochemical reactions.

Appendix A: Derivation of parametric sensitivities (Eqs. 23, 27, 31 and 35) for the quadratic kinetics

Using the definition of $y = K_{ES} + [E]_T + [S]_T$ and $x = 4[E]_T [S]_T / y^2$, one has the following results

$$v_{QD} = \frac{k_2^2 y}{2} \left(1 - \sqrt{1 - x} \right)$$

$$\frac{\partial x}{\partial k_1^+} = \frac{8[E]_T[S]_T}{(K_{ES} + [E]_T + [S]_T)^3} \frac{K_{ES}}{k_1^+} = \frac{8[E]_T[S]_T}{y^3} \frac{K_{ES}}{k_1^+}$$

$$\frac{\partial x}{\partial k_2^+} = -\frac{8[E]_T[S]_T}{(K_{ES} + [E]_T + [S]_T)^3} \frac{1}{k_1^+} = -\frac{8[E]_T[S]_T}{y^3} \frac{1}{k_1^+}$$

$$\frac{\partial x}{\partial [E]_T} = \frac{4[S]_T}{(K_{ES} + [S]_T + [E]_T)^2} - \frac{8[E]_T[S]_T}{(K_{ES} + [S]_T + [E]_T)^3} = \frac{4[S]_T}{y^2} - \frac{2x}{y}$$

$$\frac{\partial x}{\partial [S]_T} = \frac{4[E]_T}{(K_{ES} + [S]_T + [E]_T)^2} - \frac{8[E]_T[S]_T}{(K_{ES} + [S]_T + [E]_T)^3} = \frac{4[E]_T}{y^2} - \frac{2x}{y}$$

$$\frac{\partial \sqrt{1 - x}}{\partial [S]_T} = -\frac{1}{2} (1 - x)^{-1/2} \frac{\partial x}{\partial k_1^+}$$

$$\frac{\partial \sqrt{1 - x}}{\partial [E]_T} = -\frac{1}{2} (1 - x)^{-1/2} \frac{\partial x}{\partial k_2^+}$$

$$\frac{\partial \sqrt{1 - x}}{\partial [E]_T} = -\frac{1}{2} (1 - x)^{-1/2} \frac{\partial x}{\partial [E]_T}$$

$$\frac{\partial \sqrt{1 - x}}{\partial [S]_T} = -\frac{1}{2} (1 - x)^{-1/2} \frac{\partial x}{\partial [S]_T}$$

$$\frac{\partial \sqrt{1 - x}}{\partial [S]_T} = -\frac{1}{2} (1 - x)^{-1/2} \frac{\partial x}{\partial [S]_T}$$

$$\frac{\partial \sqrt{1 - x}}{\partial [S]_T} = -\frac{1}{2} (1 - x)^{-1/2} \frac{\partial x}{\partial [S]_T}$$

(A1)

(A2)

(A3)

(A4)

(A5)

(A6)

(A7)

(A8)

(A9)

(A10)

$$\frac{\partial y}{\partial k_2^+} = \frac{\partial K_{ES}}{\partial k_2^+} = \frac{1}{k_1^+}$$
$$\frac{\partial y}{\partial [E]_T} = \frac{\partial y}{\partial [S]_T} = 1$$

10

Then from Eq. (A1), one has

$$\frac{\partial v_{\text{QD}}}{\partial k_2^+} = \frac{y}{2} \left(1 - \sqrt{1 - x} \right) + \frac{k_2^+}{2} \left(1 - \sqrt{1 - x} \right) \frac{\partial y}{\partial k_2^+} - \frac{k_2^+}{2} y \frac{\partial \sqrt{1 - x}}{\partial k_2^+}$$
(A13)

⁵ By substitution of Eqs. (A3), (A7) and (A11) into (A13), and use the definition of v_{QD} from Eq. (A1), one obtains

$$\frac{\partial v_{\text{QD}}}{\partial k_2^+} = \frac{y}{2} \left(1 - \sqrt{1 - x} \right) + \frac{K_{ES}}{2} \left(1 - \sqrt{1 - x} \right) - \frac{K_{ES}}{2} (1 - x)^{-1/2} x$$
$$= \frac{v_{\text{QD}}}{k_2^+} \left\{ 1 + \frac{K_{ES}}{y} - \frac{K_{ES}}{y} \left(1 - \sqrt{1 - x} \right)^{-1} (1 - x)^{-1/2} x \right\}$$
(A14)

which, after some rearrangements, gives Eq. (23) in the main text. Similarly, from Eq. (A1), one has

$$\frac{\partial v_{\text{QD}}}{\partial k_1^+} = \frac{k_2^+}{2} \left(1 - \sqrt{1 - x} \right) \frac{\partial y}{\partial k_1^+} - \frac{k_2^+ y}{2} \frac{\partial \sqrt{1 - x}}{\partial k_1^+}$$
(A15)

which, after using Eqs. (A2), (A6) and (A10), leads to

$$\frac{\partial v_{\text{QD}}}{\partial k_1^+} = -\frac{1}{2} K_{ES}^2 \left(1 - \sqrt{1 - x} \right) + \frac{1}{2} K_{ES}^2 (1 - x)^{-1/2} x$$
$$= \frac{v_{\text{QD}}}{k_1^+} \left\{ -\frac{K_{ES}}{y} + \frac{K_{ES}}{y} (1 - x)^{-1/2} \left(1 - \sqrt{1 - x} \right)^{-1} x \right\}$$

Tang Title Page Abstract Introduction Conclusions References **Discussion** Paper **Tables** Figures 14 Back Full Screen / Esc **Discussion** Paper Printer-friendly Version Interactive Discussion

(A11)

(A12)

(A16)

By multiplying k_1^+/v_{QD} to both side of Eq. (A16), one easily obtains Eq. (27). Take the partial derivative with respect to $[E]_T$ in Eq. (A1), one obtains

$$\frac{\partial v_{\text{QD}}}{\partial [E]_T} = \frac{k_2^+}{2} \left(1 - \sqrt{1 - x} \right) \frac{\partial y}{\partial [E]_T} - \frac{k_2^+ y}{2} \frac{\partial \sqrt{1 - x}}{\partial [E]_T}$$
(A17)

which, when combined with Eqs. (A4), (A8), and (A12), becomes

$$5 \quad \frac{\partial v_{\text{QD}}}{\partial [E]_{T}} = \frac{k_{2}^{+}}{2} \left(1 - \sqrt{1 - x} \right) + \frac{k_{2}^{+}}{2} (1 - x)^{-1/2} \left(\frac{2[S]_{T}}{y} - x \right)$$
$$= \frac{v_{\text{QD}}}{[E]_{T}} \left\{ \frac{[E]_{T}}{y} + \frac{[E]_{T}}{y} \left(1 - \sqrt{1 - x} \right)^{-1} (1 - x)^{-1/2} \times \left(\frac{2[S]_{T}}{y} - x \right) \right\}$$
(A18)

from which, after some rearrangement, one finds Eq. (31).

Note, because switching the order of $[E]_T$ and $[S]_T$ in Eq. (A1) does not change the definition of v_{QD} , Eq. (35) could be derived from Eq. (31) by simply swapping $[E]_T$ and $[S]_T$.

Appendix B: Derivation of parametric sensitivities (Eqs. 24, 28, 32, and 36) for the Equilibrium Chemistry Approximation kinetics

7683

Using the definitions of x and y, v_{ECA} is

$$v_{\rm ECA} = \frac{k_2^+[E]_T[S]_T}{y}$$

10

¹⁵ From Eq. (B1), one has

$$\frac{\partial v_{\text{ECA}}}{\partial k_2^+} = \frac{[E]_T[S]_T}{y} - \frac{k_2^+[E]_T[S]_T}{y^2} \frac{\partial y}{\partial k_2^+}$$

Discussion Paper **GMDD** 8,7663-7691,2015 **Relationships** between substrate **kinetics** Discussion Paper J. Y. Tang Title Page Abstract Introduction References **Discussion Paper** Tables **Figures** Back Full Screen / Esc Discussion Paper **Printer-friendly Version** Interactive Discussion

(B1)

(B2)

which, when combined with Eq. (A11), becomes

$$\frac{\partial v_{\text{ECA}}}{\partial k_2^+} = \frac{v_{\text{ECA}}}{k_2^+} - \frac{v_{\text{ECA}}}{k_2^+} \frac{K_{ES}}{y}$$

The by dividing both sides of Eq. (B2) with v_{ECA}/k_2^+ , one obtains Eq. (24). Similarly, from Eq. (B1), one has

$$\frac{\partial v_{\text{ECA}}}{\partial k_1^+} = -\frac{k_2^+[E]_T[S]_T}{y^2} \frac{\partial y}{\partial k_1^+}$$

5

10

Then by aid of Eq. (A10), one finds

$$\frac{\partial v_{\text{ECA}}}{\partial k_1^+} = \frac{v_{\text{ECA}}}{k_1^+} \frac{K_{ES}}{y}$$

which gives Eq. (28) by multiplying k_1^+/v_{ECA} to both sides. For $[E]_{T}$, one can derive from Eq. (B1)

$$\frac{\partial v_{\text{ECA}}}{\partial [E]_T} = \frac{k_2^+[S]_T}{y} - \frac{k_2^+[E]_T[S]_T}{y^2} \frac{\partial y}{\partial [E]_T}$$

which, when combined with Eq. (A12), leads to

 $\frac{\partial v_{\text{ECA}}}{\partial [E]_T} = \frac{v_{\text{ECA}}}{[E]_T} - \frac{v_{\text{ECA}}}{y}$

One then, by dividing both sides of Eq. (B7) with $v_{ECA}/[E]_T$, obtains Eq. (32).

By using the symmetry between $[E]_T$ and $[S]_T$ in the definition of v_{ECA} , Eq. (36) could be obtained by swapping $[E]_{\tau}$ and $[S]_{\tau}$ in Eq. (32).

Author contributions. J. Y. Tang developed the theory, conducted the analyses, and wrote th paper.
