

# Spatio-temporal approach to moving window block kriging of satellite data

Jovan M. Tadić<sup>1</sup>, Xuemei Qiu<sup>1</sup>, Scot Miller<sup>1</sup> and Anna M. Michalak<sup>1</sup>

[1]{Department of Global Ecology, Carnegie Institution for Science, Stanford, CA 94305, USA}

**Abstract.** Numerous existing satellites observe physical or environmental properties of the Earth system. Many of these satellites provide global-scale observations, but these observations are often sparse and noisy. By contrast, contiguous, global maps are often most useful to the scientific community (i.e., level 3 products). We develop a spatiotemporal moving window block kriging method to create contiguous maps from sparse and/or noisy satellite observations. This approach exhibits several advantages over existing methods: 1) it allows for flexibility in setting the spatial resolution of the level 3 map, 2) it is applicable to observations with variable density, 3) it produces a rigorous uncertainty estimate, 4) it exploits both spatial and temporal correlations in the data, and 5) it facilitates estimation in real time. Moreover, this approach only requires the assumption that the observable quantity exhibits spatial and temporal correlations that are inferable from the data. We test this method by creating Level 3 products from satellite observations of CO<sub>2</sub> (XCO<sub>2</sub>) from the Greenhouse Gases Observing Satellite (GOSAT), CH<sub>4</sub> (XCH<sub>4</sub>) from the Infrared Atmospheric Sounding Interferometer (IASI) and solar-induced chlorophyll fluorescence (SIF) from the Global Ozone Monitoring Experiment–2 (GOME-2). We evaluate and analyze the difference in performance of spatio-temporal vs. recently developed spatial kriging methods.

## 1. Introduction

Satellite observations of the Earth’s surface and atmosphere provide a valuable window into the functioning of the Earth system. Satellites often provide global observations, but these observations are rarely uniform or contiguous in space/time. The observations can be non-contiguous due to satellite orbit geometries and periods, geophysical limitations (e.g. cloud cover), and temporary instrument malfunctions. Furthermore, satellites may provide a large quantity of data, but individual observations can have a large noise-to-signal ratio. It is often necessary to spatially interpolate the data in order to organize the data onto a regular grid, query the data at a particular location of interest, estimate data at unsampled times and/or locations, and/or map the underlying signal in a noisy dataset. These gridded, interpolated maps are commonly named “Level 3” data (e.g. NASA, 2014) and are often part of the standard suite of satellite data products.

CO<sub>2</sub> column observations (XCO<sub>2</sub>) from the Greenhouse Gases Observing Satellite (GOSAT), CH<sub>4</sub> column observations (XCH<sub>4</sub>) from the Infrared Atmospheric Sounding Interferometer (IASI) and solar-induced chlorophyll fluorescence (SIF) observations from The Global Ozone Monitoring Experiment–2 (GOME-2) provide prototypical examples of these challenges, and these three satellites are the primary application used throughout this work (see Section 3).

The most commonly-used method for creating Level 3 maps from satellite data is binning. This approach involves taking the mean of all observations within a given grid cell or “bin” (see Kulawik et al., 2010, and Crévoisier et al., 2009 for examples). The binning method, however, has a number of shortfalls that can lead to inconsistent or inaccurate results. First, different bins contain variable numbers of observations. As a result, some bins will be well-constrained by the data while others may be based upon sparse, noisy

41 observations. Second, binning does not produce uncertainty estimates. Third, this method cannot  
42 extrapolate the unknown quantity to bins without any observations.

43 A broad class of geostatistical methods known as kriging provides an alternative approach to mapping  
44 satellite observations. Kriging is a best linear unbiased estimator (for kriging see Chiles and Delfiner, 2012),  
45 where covariance functions are used to represent correlations among data. As a result, kriging can account  
46 for a variable density of observations and can estimate uncertainties in the resulting maps. Various forms  
47 of kriging have recently been used to map satellite Earth observations, particularly for XCO<sub>2</sub> (e.g.,  
48 Hammerling et al. 2012a,b; Tadić et al., 2015; Zeng et al., 2013; Guo et al., 2013, Zeng et al., 2016).  
49 Hammerling et al. (2012a,b) presented an approach to map Orbiting Carbon Observatory-2 (OCO-2) and  
50 GOSAT XCO<sub>2</sub> observations, respectively, with non-stationary properties. In our previous study (Tadić et  
51 al., 2015) we extended that approach to create XCO<sub>2</sub> maps that can have a different spatial resolution from  
52 the resolution or footprint of the original satellite observations. Our previous study and those of  
53 Hammerling et al. (2012a,b) accounted for spatial covariances among observations but did not include a  
54 temporal component. The present study extends this geostatistical framework from a purely spatial to a  
55 spatiotemporal domain.

56 Spatiotemporal approaches to interpolation can provide a number of advantages relative to purely spatial  
57 methods (e.g. Zeng et al., 2016; Guo et al., 2013). A purely spatial approach will usually aggregate  
58 observations into temporal blocks; observations within the same block effectively have the same time stamp  
59 whether or not those observations are actually synchronous (e.g., Tadić et al., 2015; Hammerling et al.,  
60 2012a,b). Any real temporal variability within a block becomes noise. A spatiotemporal approach, by  
61 contrast, treats time as an explicit dimension and models covariances among data as a function of time.

62 A handful of recent studies have considered temporal relationships when mapping satellite observations of  
63 XCO<sub>2</sub>. These studies have either used various forms of Kalman smoothing (e.g., Katzfuss and Cressie 2011,  
64 Katzfuss and Cressie 2012, Nguyen et al. 2014) or geostatistics (e.g., Guo et al. 2013; Zeng et al. 2013;  
65 Zeng et al. 2016). The former group of studies leverages Kalman smoothing to improve the computational  
66 tractability of mapping dense or abundant datasets, like OCO-2 and the Atmospheric Infrared Sounder  
67 (AIRS). The latter group of studies, by contrast, has applied geostatistics to sparse datasets like those from  
68 the GOSAT satellite. A detailed review of spatial and spatio-temporal mapping methods has been published  
69 recently (Li and Heap, 2014).

70 The goal of this study is to develop a geostatistical spatio-temporal mapping and upscaling method  
71 (applicable, but not limited to, satellite observations of XCO<sub>2</sub>) that exhibits several advances relative to  
72 previous methods. It can: (1) fill in temporal gaps in the observations, (2) create maps at higher temporal  
73 resolutions than purely spatial approach, (3) produce more accurate estimates when observations have  
74 variable spatio-temporal coverage, (4) predict future values (i.e. extrapolate temporally). Among other  
75 improvements, we develop an efficient method for subsampling satellite observations and utilize the  
76 product-sum covariance model (e.g., De Iaco et al., 2001) that is easy to parameterize, which makes it  
77 applicable to both dense and sparse datasets. The entire work has been conducted in Matlab 2012a.

78 Section 2 of this study describes the presented model in detail; it describes an efficient subsampling  
79 procedure that can handle very large datasets and a covariance model that can estimate both spatial and  
80 temporal relationships in the data. We then incorporate these components into a spatiotemporal version of  
81 moving window block kriging. In sections 3 and 4, we subsequently apply this model to map GOSAT  
82 XCO<sub>2</sub>, IASI XCH<sub>4</sub> and GOME-2 SIF at multiple time resolutions (including daily).

## 83 2. Methods

84 The spatio-temporal block kriging approach presented in this study proceeds in three steps for each model  
85 grid cell and estimation time. First, we subsample the observations within a predetermined spatio-temporal  
86 domain (section 2.1). Next, we characterize the local spatio-temporal covariance structure (section 2.2).  
87 Finally, we interpolate the satellite observations at the desired spatial resolution (section 2.3).

### 88 2.1 Subsampling of observations

89 The ultimate goal of the proposed subsampling strategy is to reduce the number of observations in the  
90 spatio-temporal vicinity of an estimation location to a representative, computationally feasible subset of  
91 data. We use a subset of observations ( $M$ ) to estimate a local set of covariance parameters and use another  
92 subset ( $N$ ) to estimate the desired quantity and associated uncertainty. Note that, for the method presented  
93 here,  $M$  and  $N$  can refer to either the same subset of data or different subsets.

94 The total number of observations used for covariance parameter estimation ( $M$ ), is selected to be small  
95 enough to make this estimation computationally feasible but large enough to yield a sample representative  
96 of both local and regional variability. The optimal subset of  $N$  observations used for mapping depends on  
97 the actually observed covariance structure which is not known prior to covariance parametrization step. In  
98 the example presented in Sect. 3, the optimal observational subset used in a mapping step for each grid cell  
99 comprised  $N$  points having the highest covariance with the estimation location. In the example below, we  
100 set both  $M$  and  $N$  at 500; larger values of  $M$  and  $N$  did not have a substantial impact on the estimated  
101 parameters and mapped quantity, respectively.

102 We select subset of observations  $M$  for each estimation grid cell by assigning a relative selection probability  
103 to each observation based on that observation's spatial and temporal 'separation distances' from the  
104 centroid of the grid cell. In the absence of a proper metric for distance in space-time, we model the spatial  
105 and temporal components of the overall selection probability separately.

106 The selection probability (and its components) is described by the following equation:

$$107 \quad P = P_s \times P_t \propto 1/(A_s h_s)^2 \times e^{-(A_t h_t)^2} \quad (1)$$

108 where  $P_s$  is the spatial component of the relative probability of a given observation being selected,  $P_t$  is  
109 temporal component,  $h_s$  and  $h_t$  are distances between estimation location and observations, in space and  
110 time, respectively, and  $A_s$  and  $A_t$  are unit dependent, user defined weighting factors between separation  
111 distance in space vs. in time (how deep in space vs. time the sampling should occur). The unit dependent  
112 choice of  $A_s$  and  $A_t$  can be initially based on user expectations of the decorrelation distances in space vs.  
113 time and, if necessary, subsequently corrected accounting for actually computed decorrelation lengths in  
114 space and time in an iterative fashion. In this way temporal and spatial sampling depths could even be  
115 locally optimized and become location-specific. In the examples below (Section 3),  $A_s$  and  $A_t$  were set to 1  
116  $\text{km}^{-1}$ , and  $0.5 \text{ day}^{-1}$ , respectively, based on the observed average decorrelation distances in space and time  
117 (see Fig. 1 and Section 4.1).

118 [Figure 1]

120  $h_s$  is calculated as the great circle distance between the centroid  $x_j$  of the estimation grid cell and the location  
121  $x_i$  of an observation:

122 
$$h_s(x_i, x_j) = r \cos^{-1}(\sin \varphi_i \sin \varphi_j + \cos \varphi_i \cos \varphi_j \cos(\lambda_i - \lambda_j)) \quad (2)$$

123 where  $\varphi_i$  and  $\lambda_i$  are the latitude and longitude of location  $x_i$  and  $r$  is the radius of the Earth.

124 The temporal and spatial components of the probability function have different functional forms out of  
125 necessity. The measurements often come pre-aggregated in time slices corresponding to hours, days, or  
126 longer aggregation time periods, which multiplies the number of observations with the same time stamp.  
127 As a result, it is not possible to assign sampling probability along a temporal axis in a manner equivalent to  
128 the spatial approach; doing so would result in infinite probabilities assigned to all observations within the  
129 time slice of the actual estimation location ( $P_t \sim 1/0^2 = \infty$ ). The same holds for spatially co-located  
130 observations. However, since each observation comes with unique spatial coordinates (not pre-binned like  
131 in temporal case), we select a simpler form of the spatial component of the sampling function. The defined  
132 form of  $P$  (Eq. 1) ensures that pairs of observations close to estimation location define the shape of the  
133 variogram at short separation distances (the variogram should reflect variability in the spatio-temporal  
134 vicinity of the estimation grid cell. See Section 2.2). Different forms of  $P$  can be used if directional  
135 anisotropy is expected or if more/fewer observations along a given direction are desired to better represent  
136 expected correlations.

137 Previous approaches required the user to choose spatial and temporal windows that determine which  
138 neighboring observations to use (see, for comparison, Alkhaled et al. 2008; Hammerling et al. 2012a,b).  
139 The approach proposed in this paper, by contrast, requires fewer subjective choices – only the form of  
140 sampling function and unit dependent choice of normalizing coefficients  $A_s$  and  $A_t$ . In addition, our  
141 approach is computationally feasible even for very large data sets.

## 142 **2.2 Characterization of Spatio-temporal Covariance**

143 Existing studies have used a number of models to estimate spatio-temporal covariances for a variety of  
144 applications. Models used include the metric model (Dimitrakopoulos and Luo, 1994), linear model  
145 (Rouhani and Hall, 1989), product model (De Cesare et al., 1996), non-separable model (Cressie and  
146 Huang, 1999), and generalized product-sum covariance model (De Iaco et al., 2001). The approach  
147 developed in this paper uses a generalized product-sum covariance model (De Iaco et al., 2001). This model  
148 affords a number of advantages relative to other covariance models: (1) a product sum covariance model  
149 outperformed other models in terms of prediction accuracy in a recent study using GOSAT satellite data  
150 (Guo et al., 2013), (2) it is relatively easy to implement (De Iaco et al., 2001), and (3) it is more flexible  
151 than a non-separable covariance model (De Cesare, 2001a).

152 The product-sum model, as it has been applied in the past, has one important area for improvement. The  
153 original procedure (De Iaco et al., 2001) assumed separate modeling of the spatial and temporal covariance  
154 (variograms) and their later unification into a spatio-temporal model in the final step. The procedure  
155 requires observations approximately in the same location at multiple different times. However, satellite  
156 observations are often not perfectly collocated in consequent measurement cycles over the same region. As  
157 a result, we would need to assume that each measurement cycle is perfectly co-located with previous/future  
158 cycles, or define an arbitrary tolerance, in order to apply the original approach. This assumption becomes  
159 more prone to error if the observations are very sparse, as is often the case with satellites.

160 Thus, in this study, we cater to specific properties of satellite data and alter the original procedure by  
161 estimating all covariance parameters simultaneously, thereby avoiding the aforementioned problem.

162 We broadly define the covariance as follows:

163 
$$C_{s,t}(h_s, h_t) = \text{Cov}(Z(s+h_s, t+h_t), Z(s, t)) \quad (3)$$

164 The equation shows that covariance between two points ( $Z$ ) separated in space-time ( $s, t$ ) depends on their  
 165 distance in space ( $h_s$ ) and distance in time ( $h_t$ ). The following class of valid product–sum covariance models  
 166 was introduced in De Cesare et al. (2001b) and further developed in De Iaco et al. (2001):

167 
$$C_{s,t}(h_s, h_t) = k_1 C_s(h_s) C_t(h_t) + k_2 C_s(h_s) + k_3 C_t(h_t) \quad (4)$$

168 where  $C_t$  and  $C_s$  are valid temporal and spatial covariance models, respectively. De Iaco et al. (2001) proved  
 169 that for positive definiteness it is sufficient that  $k_1 > 0$ ,  $k_2 \geq 0$  and  $k_3 \geq 0$ . It is interesting to note that from  
 170 Eq. 4 follows that spatio-temporal covariance models collapses down to purely spatial model in cases where  
 171 temporal covariance does not exist. Thus, the spatial approach could be viewed as a special case of spatio-  
 172 temporal modeling.

173 The model in Eq. 4 corresponds to the spatio-temporal variogram shown in Equation 5. In the original  
 174 procedure, De Iaco et al., 2001 estimated separate spatial ( $h_t=0$ ) and temporal ( $h_s=0$ ) variograms using the  
 175 data. De Iaco et al., 2001 then combined these models to obtain the final spatio-temporal variogram model:

176 
$$\gamma_{s,t}(h_s, h_t) = \gamma_{s,t}(h_s, 0) + \gamma_{s,t}(0, h_t) - k \gamma_{s,t}(h_s, 0) \gamma_{s,t}(0, h_t) \quad (5)$$

177 where  $\gamma_{s,t}(h_s, 0)$  and  $\gamma_{s,t}(0, h_t)$  are spatio-temporal variograms for  $h_t=0$  and  $h_s=0$ , respectively (Figure 2).  
 178 Parameter  $k$  is estimated from the data which makes the model easily applicable:

179 
$$k = \frac{k_s C_s(0) + k_t C_t(0) - C_{s,t}(0,0)}{k_s C_s(0) k_t C_t(0)} \quad (6)$$

180 where  $k_s C_s(0)$  and  $k_t C_t(0)$  are spatial and temporal sills (variances) obtained in modeling of separate  
 181 spatial and temporal variograms. The only condition  $k$  has to fulfill in order to create an admissible  
 182 covariance model is

183 
$$0 < k \leq \frac{1}{\max\{\sigma_s^2(\gamma_{s,t}(h_s, 0)); \sigma_t^2(\gamma_{s,t}(0, h_t))\}} \quad (7)$$

184 Due to the specifics of satellite data, we estimate both the covariance parameters and parameter  $k$   
 185 simultaneously. This approach accounts for constraints that assure a positive definiteness of the model (De  
 186 Iaco et al., 2001). This simultaneous approach makes the model more applicable to sparse data and data  
 187 with variable spatial coverage, as is often the case with satellite observations.

188 We use a Gaussian variogram function with a nugget effect to model temporal covariance in the example  
 189 presented here (for an overview of variogram models see Chiles and Delfiner, 2012). We use an exponential  
 190 model for the spatial variogram. In both cases, we make this choice based upon visual inspection of local  
 191 variograms at multiple estimation locations:

192 
$$\gamma_t(h_t)(\text{Gaussian}) = \begin{cases} 0, & \text{for } h_t = 0 \\ \sigma_t^2 (1 - \exp(-\frac{h_t^2}{l_t^2})) + \sigma_{nug}^2, & \text{for } h_t > 0 \end{cases} \quad (8)$$

193 
$$\gamma_s(h_s)(\text{exponential}) = \begin{cases} 0, & \text{for } h_s = 0 \\ \sigma_s^2 (1 - \exp(-\frac{h_s}{l_s})) + \sigma_{nug}^2, & \text{for } h_s > 0 \end{cases} \quad (9)$$

194 where  $\sigma^2$  and  $l$  are the variance and correlation length of the quantity being mapped, and  $\sigma_{nug}^2$  is the nugget  
 195 variance, typically representative of measurement and retrieval errors in the case of satellite observations.

196 [Figure 2]

197 Unlike the original procedure in De Iaco et al. (2001), we model the variogram using only two steps. First,  
 198 we calculate a raw spatio-temporal variogram based on the subsampled observations for each estimation  
 199 grid cell:

$$200 \quad \gamma(h_s, h_t) = \frac{1}{2}[y(x_i) - y(x_j)]^2 \quad (10)$$

201 where  $\gamma$  is the raw spatio-temporal variogram value for a given pair of observations  $y(x_i)$  and  $y(x_j)$ , and  $h_s$   
 202 and  $h_t$  are, respectively, the great circle distance and temporal distance between the spatio-temporal  
 203 locations ( $x_i$  and  $x_j$ ) of these observations.

204 Second, we fit the theoretical variogram defined in Eq. 5 to the raw variogram using non-linear least  
 205 squares. We subsequently calculate the spatiotemporal covariance using the following equation:

$$206 \quad C_{s,t}(h_s, h_t) = C_{s,t}(0,0) - \gamma_{s,t}(h_s, h_t) \quad (11)$$

207 **Validity on the sphere.** Most covariance models were originally designed for Euclidean space, and their  
 208 validity in other coordinate systems cannot be assumed *per se*. Huang et al. (2011) examined the validity  
 209 of several theoretical covariance models in spherical coordinate systems. However, this evaluation has not  
 210 been done for the spatio-temporal product-sum covariance model. Other studies that use a product-sum  
 211 covariance model typically assume the validity of this covariance model on a sphere (e.g., Zeng et al., 2013;  
 212 Zeng et al., 2016). Results from Huang et al. (2011) explicitly validate the exponential covariance model  
 213 on a sphere, as well as sums of the products of exponential covariance models and constants (provided that  
 214 the constants are positive). The first term of the product-sum covariance model used in this study (Eq. 4)  
 215 represents a Hadamard product (Million, 2007) of two positive definite matrices. According to Schur  
 216 product theorem, a Hadamard product of two positive definite matrices necessarily gives a positive definite  
 217 matrix (Mathias, 1993). It therefore follows that a generalized product-sum model (Equation 4) is valid on  
 218 a sphere if its spatial component is valid on a sphere.

### 219 **2.3 Mapping using spatio-temporal moving window block kriging**

220 This section leverages the sampling function (Sect. 2.1) and the product-sum covariance model (Sect. 2.2)  
 221 to implement a spatio-temporal version of moving window block kriging. A primary advantage of block  
 222 kriging is its ability to estimate contiguous maps at any spatial resolution equal to or coarser than the spatial  
 223 support (i.e. footprint size) of observations (refer to Sect. 1 and Tadić et. al. 2015). Unlike ordinary kriging  
 224 method, the spatial support in block kriging corresponds to the average value within each chosen grid cell.

225 Moving window block kriging requires solving a set of linear equations to obtain a set of weights ( $\lambda$ ). These  
 226 weights must be estimated for each prediction location using  $N$  associated observations:

$$227 \quad \begin{bmatrix} \mathbf{Q} + \mathbf{R} & \mathbf{1} \\ \mathbf{1}^T & 0 \end{bmatrix} \begin{bmatrix} \lambda \\ -\nu \end{bmatrix} = \begin{bmatrix} \mathbf{q}_A \\ 1 \end{bmatrix} \quad (12)$$

228 In this equation,  $\mathbf{R}$  is a diagonal  $N \times N$  nugget covariance matrix that describes measurement and retrieval  
 229 errors,  $\mathbf{Q}$  is a  $N \times N$  covariance matrix among the  $N$  observations with individual entries as defined in Eqn.  
 230 11,  $\mathbf{1}$  is an  $N \times 1$  unity vector,  $\nu$  is a Lagrange multiplier, and  $\mathbf{q}_A$  is an  $N \times 1$  vector of the spatio-temporal  
 231 covariances between the  $N$  observation locations and the estimation grid cell, defined as:

232 
$$q_{A,i} = \frac{1}{n} \sum_{j=1}^n q(h_{s_{i,j}}, h_{t_{i,j}}) \quad (13)$$

233 where  $q_{A,i}$  is the covariance between the grid cell and observation  $i$ .  $q(h_{i,j})$  is defined as  $C_{s,t}$  in Eqn. 11  
 234 based on the distances  $h_{s_{i,j}}$  and  $h_{t_{i,j}}$  between observation  $i$  and  $n$  regularly-spaced locations within the grid  
 235 cell. In the context of satellite measurements,  $n$  is a highest number of non-overlapping footprints contained  
 236 within a grid cell and was calculated based on the relative size of the satellite footprint compared to the  
 237 size of the estimation grid cells.  $n$  varies with latitude, as the size of grid cells decreases with the distance  
 238 from the equator. The system in Eqn. 12 is solved for the weights ( $\lambda$ ) and the Lagrange multiplier ( $\nu$ ). We  
 239 subsequently use these parameters to define the estimate ( $\hat{z}$ ) and estimation uncertainty ( $\sigma^2_{\hat{z}}$ ) for the grid  
 240 cell:

241 
$$\hat{z} = \lambda^T \mathbf{y} \quad (14)$$

242 
$$\sigma^2_{\hat{z}} = \sigma_{AA} - \lambda^T \mathbf{q}_A + \nu \quad (15)$$

243 where  $\mathbf{y}$  is the  $N \times 1$  vector of subsampled observations, and  $\sigma_{AA}$  is the variance of the observations at the  
 244 resolution of the estimation grid cell, defined as:

245 
$$\sigma_{AA} = \frac{1}{n^2} \sum_{j=1}^n \sum_{k=1}^n q(h_{j,k}) \quad (16)$$

246 In that equation,  $q(h_{s_{i,j}}, h_{t_{i,j}})$  is defined as  $C_{s,t}$  in Eqn. 11 based on the distances  $h_{s_{i,j}}$  and  $h_{t_{i,j}}$  between  
 247 any combination of the  $n$  regularly spaced locations within the grid cell defined previously.

### 248 3. Example applications

249 We select three case studies of satellite Level 2 data to demonstrate the properties of the method developed  
 250 in this paper: column-integrated dry air model fraction of CO<sub>2</sub> (XCO<sub>2</sub>) from the Japanese Greenhouse Gas  
 251 Observing SATellite (GOSAT), CH<sub>4</sub> (XCH<sub>4</sub>) from the Infrared Atmospheric Sounding Interferometer  
 252 (IASI), and solar-induced fluorescence (SIF) the Global Ozone Monitoring Experiment–2 (GOME-2).  
 253 Level 2 datasets from GOSAT, IASI and GOME-2 have relatively different characteristics. For example,  
 254 GOSAT observations are sparse while IASI and GOME-2 are abundant. These diverse datasets are therefore  
 255 ideal for testing the method developed here.

256 The method was demonstrated by producing two different sets of maps. First, it was applied at resolutions  
 257 coarser than native ( $1 \times 1^\circ$ ,  $2.5 \times 2^\circ$ , and  $1 \times 1^\circ$  for GOSAT, IASI and GOME-2, respectively) to  
 258 demonstrate block kriging capabilities of the method (Section 3). Second, it was applied at the native  
 259 resolution of the satellites for cross-validation (method evaluation) purposes (Section 4).

#### 260 3.1 Total column CO<sub>2</sub> (XCO<sub>2</sub>) observed by GOSAT

261 The Japanese Greenhouse Gas Observing SATellite (GOSAT) (e.g., Kuze et al., 2009), the first satellite  
 262 dedicated to global greenhouse gas monitoring, was launched in 2009. Basic information about the satellite,  
 263 its orbit configuration, and the CO<sub>2</sub> column observations are given in our previous study (Tadić et al., 2014).  
 264 It flies in a polar, sun-synchronous orbit with a 3-day repeat cycle and an approximate 13:00 LT overpass  
 265 time. GOSAT has a nadir footprint of about 10.5 km diameter at sea level (Kuze et al., 2009) and  $2 \times 10^3$

266 observations per week. The XCO<sub>2</sub> observations from GOSAT have large retrieval uncertainties (e.g.,  
267 O’Dell et al. 2012) and exhibit large spatial and temporal gaps (e.g., Fig. 3a). Although these XCO<sub>2</sub>  
268 observations are sparse and noisy, contiguous Level 3 maps are often desirable for environmental and  
269 ecological applications (Maksyutov et al., 2013; Liu et al., 2012). To this end, we generate global daily  
270 estimates for XCO<sub>2</sub> (August 2-7, 2009) to match the timeframe used in Tadić et al., 2014.

271 [Figure 3]

272 We obtain bias-corrected and filtered GOSAT Level 2 observations using NASA’s Atmospheric CO<sub>2</sub>  
273 Observations from Space (ACOS) algorithm v3.4 release 3 (e.g., O’Dell et al., 2012; Crisp et al., 2012). In  
274 this study, we use spatio-temporal moving window block kriging to create a series of contiguous, in-filled  
275 global daily maps and associated uncertainties for 2-7 August 2009 (two repeat cycles) (Fig. 3a-c) at 1°×1°  
276 resolution. We select the time period to match the time period from our previous study (Tadić et al., 2014).  
277 Unlike results from our previous study and other similar studies, which created estimates at 6-day or longer  
278 time periods (Hammerling et al., 2012a), we leverage the method developed here to produce maps at the  
279 daily scale.

### 280 **3.2 Total column CH<sub>4</sub> (XCH<sub>4</sub>) observed by IASI**

281 The Infrared Atmospheric Sounding Interferometer (IASI) developed by the Centre National d’Etudes  
282 Spatiales (CNES) in collaboration with the European Organisation for the Exploitation of Meteorological  
283 Satellites (EUMETSAT) is a Fourier Transform Spectrometer based on a Michelson Interferometer coupled  
284 to an integrated imaging system that measures infrared radiation emitted from the Earth. It is carried by  
285 MetOp-A, a sun-synchronous polar orbit satellite which flows at an altitude of 817 km. Detailed information  
286 about the IASI instrument could be found elsewhere (Crévoisier et al., 2009a,b; Massart et al., 2014). IASI  
287 has an instantaneous field of view of 50×50 km, composed of four pixels each 12 km in radius, delivering  
288 ~56×10<sup>3</sup> XCH<sub>4</sub> observations per week.

289 [Figure 4]

290 Methane Level 2 IASI (0-4 km) data were retrieved at the NOAA/NESDIS using the NUCAPS (NOAA  
291 Unique CrIS/ATMS Processing System) algorithm (Gambacorta, 2013; Xiong et al., 2013). For the ice-  
292 covered ocean the data for the lower troposphere (0-4 km) are unreliable due to insufficient thermal contrast  
293 between the surface and the atmosphere. Filtering parameters have been provided by Xiong (2014, private  
294 communication). The data are available at <http://www.nsof.class.noaa.gov/>. Using the new method, we  
295 created a series of contiguous global daily maps and associated uncertainties for the Northern Hemisphere,  
296 for February 26-March 4, 2013 (i.e. Figure 4a-c) at 1°×1° resolution. We chose this time period to match  
297 the occurrence of the methane “anomaly” North of the coast of Scandinavia.

### 298 **3.3 Global land solar-induced fluorescence fields observed by GOME-2**

299 The GOME-2 (The Global Ozone Monitoring Experiment–2) instrument on board METOP-A (e.g., Joiner  
300 et al., 2013) observes solar-induced fluorescence (SIF). The GOME-2 spatial footprint (i.e. support) of the  
301 observations is 40 km × 80 km (Joiner et al, 2013), and the volume of available data is approximately 2×10<sup>5</sup>  
302 SIF observations per week.

303 [Figure 5]

304 Multiple recent studies have demonstrated the potential use of satellite observations of solar-induced  
305 fluorescence (SIF) for understanding the photosynthetic CO<sub>2</sub> uptake at large scales (Joiner et al., 2011;  
306 Joiner et al., 2012; Joiner et al., 2013; Frankenberg et al., 2011; Frankenberg et al., 2012; Guanter et al.,  
307 2012, Lee et al., 2013; Frankenberg et al., 2014). Satellite SIF measurements can be used with land surface  
308 models to understand GPP response to environmental stress (e.g., Lee et al., 2013) and to improve the  
309 representation of GPP. GOME-2 provides the highest spatial and temporal density of data, among all  
310 available datasets.

311 In the example presented here we use SIF GOME-2 v.14 data (Joiner et al., 2013) with the approach  
312 described in Section 2 to create contiguous maps of SIF at a single spatial resolution (1° × 1°) and daily  
313 temporal resolutions. Maps of SIF and associated uncertainties are created at daily temporal resolutions  
314 covering 5-14 May, 2012, some of which are shown on Figures 5a-c.

## 315 **4. Method evaluation: accuracy, precision and bias**

### 316 **4.1 Accuracy, precision and bias**

317 We use a leave-one-out cross validation technique to assess the performance of spatio-temporal (ST) versus  
318 spatial moving window block kriging. We produce these estimates at the native resolution of GOSAT, IASI  
319 and GOME-2 satellites/instruments, which allowed a direct comparison to measured values. For IASI and  
320 GOME-2, for each day in February 26-March 4, 2013, and May 5-14, 2012, respectively, 10% of available  
321 observational data were randomly selected for use in leave-one-out cross-validation and their coordinates  
322 extracted. For XCO<sub>2</sub>, all GOSAT XCO<sub>2</sub> observations for each day in August 2-7, 2009, were used. We  
323 assess the accuracy (the difference between estimates and withheld observations) of both methods using  
324 two common measures: (1) Mean Absolute Error (MAE), and (2) Root Mean Squared Error (RMSE). We  
325 also use two more recently proposed measures (Li and Heap, 2011; Li, 2016) that remove the effect of  
326 unit/scal. The first is relative mean absolute error (RMAE) that is given as:

327

$$328 \text{RMAE} = \frac{1}{n} \sum_{i=1}^n |(\hat{z}_i - y_i)/o_i| \times 100 \quad (17)$$

329

330 and the second is relative root mean square error (RRMSE), as follows:

331

$$332 \text{RRMSE} = \left[ \frac{1}{n} \sum_{i=1}^n (|y_i - \hat{z}_i|/y_i)^2 \right]^{1/2} \times 100 \quad (18)$$

333 where  $n$  is the number of observations or samples,  $o$  is observed value, and  $p$  is predicted or estimated value.

334 We assess the performance of each method using two additional measures: (3) the accuracy of the  
335 uncertainty bounds (the degree to which the reported uncertainties capture the difference between estimates  
336 and withheld observations) and (4) bias (the mean difference between estimates and withheld observations).

337 We parameterize the temporal component of the spatio-temporal sampling function in such a way  
338 that observations located +/- 3 days from the actual date had 10% probability of being sampled

339 compared to observations from the actual day (see Fig 1a). We compare the results to spatial  
340 kriging estimates obtained in two different ways, based on observations only from the actual day  
341 (1d) and based on observations from +/-3 days from the actual day (7d). This latter case is  
342 analogous to the +/- 3-day window that we use for the ST approach. In this 7d case, we obtain  
343 these spatial kriging results by assuming the entire observational dataset collected within the  
344 selected time period (actual day +/- 3 days) is perfectly temporally correlated. In other words, we  
345 use all observations as though they were collected at the same time. We then produce estimates at  
346 locations of observations collected within the selected timeframe and compare the performance of  
347 the two methods. We repeat procedure described in Section 2 for every observation selected for  
348 cross-validation, and we average the statistics, displayed in Table 1.

349 [Table 1]

350 According to the results, the spatio-temporal approach performs better than the spatial (7d) approach in all  
351 three cases and in all performance measures (for example, spatial (7d) MAE was 6-10% larger). The  
352 comparison clearly shows that proper characterization of the temporal covariance between two points  
353 residing in different time periods (days), embedded into spatio-temporal approach, improves kriging  
354 performance. In IASI and GOME-2 cases, the spatio-temporal method also performed better than spatial  
355 (1d). However, in case of GOSAT data, spatio-temporal approach slightly underperformed the spatial (1d)  
356 approach having 12% higher MAE (please see Section 4.2 for discussion).

357 We observed that RMAE and RRMSE error measures should be used with caution in cases when  
358 observations can take real zero values, like in the GOME-2 case. In such cases the division by close-to-zero  
359 values result in extremely high RMAE and RRMSE values, which overall limits the applicability of these  
360 error measures.

361 We evaluate the accuracy of the uncertainty bounds by examining how often those bounds encapsulate  
362 withheld observations. The percentage of observations that fall outside the uncertainty bounds in spatio-  
363 temporal approach is comparable to that of the spatial method, confirming the accuracy of the estimated  
364 uncertainty bounds (for normally-distributed data the percentage of observations that fall outside of the one,  
365 two, and three estimations standard deviation ( $\sigma_2$ ) uncertainty bounds should be 32%, 5% and 0.3%,  
366 respectively). The fraction of observations that fall outside the uncertainty bound is generally lower than  
367 would be expected for normally-distributed data, and our results may indicate non-normal features in the  
368 data.

## 369 **4.2 When is spatio-temporal modeling recommended?**

370 A ST approach can afford advantages over purely spatial methods when temporal data correlations and data  
371 coverage are strong. Indeed, in many cases, the ST approach is more accurate than a purely spatial method  
372 (Table 1). This result is consistent with existing literature which uniformly reports that ST approaches are  
373 more accurate than spatial approaches (Zeng et al., 2013; Guo et al., 2013; Zeng et al., 2016).

374 However, although considering information from days preceding and following the target estimation day  
375 should in principle always provide a further constraint on the estimate, this does not guarantee that an ST  
376 method will always outperform a spatial-only method in practice. The prime reasons for this are two-fold.  
377 First, because computational limitations cap the number of observations that can be considered, considering  
378 observations across multiple days necessarily leads to a reduction in the spatial density of observations

379 being considered. This first factor can be partially alleviated by carefully designing the selection probability  
380 function (Eqn. 1). The second reason is that implementing a ST approach involves the estimation of a larger  
381 number of covariance parameters (Eqn. 4-9) relative to a spatial-only approach, which can introduce  
382 additional uncertainty. Indeed, we observe that the purely spatial approach performs better than the ST  
383 method in some cases (e.g., the GOSAT case).

384 Overall, a ST approach is likely to outperform a spatial-only approach when the data exhibit one (or more)  
385 of three characteristics. First, a ST approach is likely better when the data are sparse or unequally  
386 distributed. In these cases, a ST approach can intelligently leverage data in adjacent time periods to  
387 compensate for the sparsity of data in the time period of interest. Second, an ST approach works well for  
388 datasets with temporal gaps (e.g., due to cloud cover or instrument malfunction). An ST approach can fill  
389 these gaps while a spatial-only approach cannot be used for temporal gap-filling. Third, an ST-approach is  
390 well-suited to datasets with regional biases that manifest in one time slice but that do not repeat in adjacent  
391 time slices. The difference between the performance of ST and S-approaches obtained through cross-  
392 validation becomes most pronounced in processing datasets with measurement errors that are spatially but  
393 not temporally correlated. In these cases, an ST approach can use data from adjacent time periods to obtain  
394 an estimate, data that do not have the same regional, spatially-correlated biases. Although the resulting  
395 estimate may appear inferior during cross-validation, this is because that estimate will not reproduce  
396 regional biases in data from the time slice of interest. A spatial-only approach, by contrast, will reproduce  
397 these regional biases because it does not use data from adjacent times when creating the estimate. As a  
398 result, a spatial-only approach will appear to perform better in cross validation, but the ST approach will  
399 more accurately reflect the true, underlying process.

## 400 **5. Conclusions**

401 In this study, we develop a method to create high spatio-temporal resolution maps from satellite data using  
402 spatio-temporal moving window block kriging based on product-sum covariance model. The method relies  
403 on a limited number of assumptions: that the observed physical quantity is spatio-temporally auto-  
404 correlated, and that its nature can be inferred from the observations.

405 The method has several advantages over previously applied methods. Apart from the advances alluded to  
406 in Sect. 1: 1) it improves covariance parameters estimation procedure because it does not model spatial and  
407 temporal covariance separately, 2) it allows for great flexibility in the choice of sampling function and 3) it  
408 provides estimates even for the time periods when measurements are not available. It can exploit  
409 correlations with both past and future periods of the observed time spot to provide the most accurate  
410 estimates.

411 We demonstrate the applicability of this method by creating Level 3 products from the GOSAT XCO<sub>2</sub>, IASI  
412 CH<sub>4</sub> and GOME-2 SIF data. Sparse XCO<sub>2</sub> observations from GOSAT and dense XCH<sub>4</sub> and SIF  
413 observations from IASI and GOME-2 make a perfect test ground for the method. We show that the proposed  
414 method can even map XCO<sub>2</sub> on daily time scales. The method generally yields more precise and accurate  
415 (and unbiased) estimates compared to spatial method which used the same observations but assumed perfect  
416 temporal correlation between data. The factors which could affect the performance of the ST method are  
417 discussed in Section 4.2.

418 This approach could be used in the future to produce real-time estimates not only of XCO<sub>2</sub>, XCH<sub>4</sub> or SIF,  
419 but of other environmental data observed by satellites which exhibit spatio-temporal autocorrelations.  
420 Especially important could be satellite datasets that have spatially, but not temporally, correlated errors. In

421 such cases, sampling across several time periods could perhaps help isolate and remove them, which should  
422 be a subject of further studies.

423 The method could be applied in a standalone mode or as part of a broader satellite data processing package.  
424 Maps produced by the spatio-temporal approach could then be incorporated into physical and  
425 biogeochemical models of the Earth system.

## 426 **6. Code availability**

427 The documented Matlab source code is available at the Researchgate website  
428 ([https://www.researchgate.net/publication/311595272\\_Spatio-](https://www.researchgate.net/publication/311595272_Spatio-temporal_approach_to_moving_window_block_kriging_of_satellite_data_v10_code)

558 **Table 1.** Cross-validation results of GOSAT XCO<sub>2</sub>, IASI XCH<sub>4</sub> and GOME-2 SIF datasets using spatio-  
559 temporal and spatial methods, including mean absolute error (MAE), root mean squared error (RMSE),  
560 relative mean absolute error (RMAE), relative root mean square error (RRMSE), percent of observations  
561 lying outside of one, two, and three standard deviations ( $\sigma_z$ ) of the mapping uncertainty, and mean  
562 difference. MAE, RMSE and bias units for GOSAT, IASI and GOME-2 are ppm, ppb and mW/m<sup>2</sup>/sr/nm,  
563 respectively. RMAE and RRMSE are unitless, and due to the reasons explained in Section 4.1 given only  
564 for GOSAT and IASI. Shaded fields represent best estimate in each category for every satellite.

GOSAT XCO <sub>2</sub>	IASI XCH <sub>4</sub>	GOME-2 SIF
------------------------	-----------------------	------------

		ST	1d	7d	ST	1d	7d	ST	1d	7d
<b>Estimates</b>	Mean absolute error (MAE)	0.83	0.74	0.89	19.19	20.23	21.04	0.52	0.54	0.54
	Root mean squared error (RMSE)	1.12	0.98	1.21	25.25	27.10	27.77	0.68	0.69	0.69
	Relative mean absolute error (RMAE)	0.22	0.19	0.23	1.04	1.09	1.14	-	-	-
	Relative root mean square error (RRMSE)	0.29	0.25	0.31	1.37	1.46	1.50	-	-	-
<b>Uncertainties</b>	% observations falling outside $1\sigma_2$ uncertainty	9.13	15.03	10.70	11.02	9.06	13.84	14.60	12.14	24.80
	% observations falling outside $2\sigma_2$ uncertainty	1.12	3.01	1.39	0.48	0.51	0.86	1.20	0.64	4.33
	% observations falling outside $3\sigma_2$ uncertainty	0.067	0.52	0.13	0.04	0.046	0.022	0.11	0.05	0.83
<b>Bias</b>	Mean difference	-0.012	0.0066	-0.034	0.28	-0.14	0.58	0.016	0.0013	0.032

567

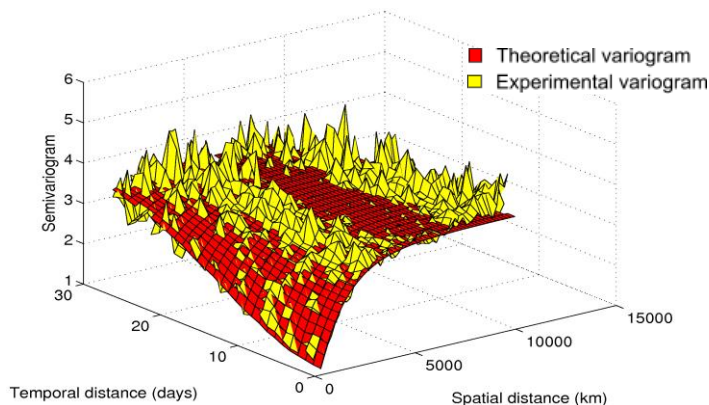

568

569 **Figure 1.** (a) Sampling probability as a decreasing function of spatial and temporal distance as used in this  
 570 study, (b) The typical example of subsampled IASI Level 2 XCH<sub>4</sub> (altitude below 4 km) data for a selected  
 571 estimation location (yellow circle). Color of observations shows semivariance between observation and  
 572 estimation location (blue-lowest, red-highest). Due to stronger temporal covariance, the relative decrease  
 573 of the sampling probability along temporal axis is smaller than with spatial distance.
