10 **Abstract**

11 Igneous intrusions in sedimentary basins may have a profound effect on the thermal structure and
12 physical properties of the hosting sedimentary rocks. These include mechanical effects such as
13 deformation and uplift of sedimentary layers, generation of overpressure, mineral reactions and
14 porosity evolution, and fracturing and vent formation following devolatilization reactions and the
15 generation of CO₂ and CH₄. The gas generation and subsequent migration and venting may have
16 contributed to several of the past climatic changes such as the end-Permian event and the Paleocene-
17 Eocene Thermal Maximum. Additionally, the generation and expulsion of hydrocarbons and cracking of
18 pre-existing oil reservoirs around a hot magmatic intrusion is of significant interest to the energy
19 industry. In this paper, we present a user-friendly 1D FEM based tool, SILLi, which calculates the thermal
20 effects of sill intrusions on the enclosing sedimentary stratigraphy. The model is accompanied by three
21 case studies of sills emplaced in two different sedimentary basins, the Karoo Basin in South Africa and
22 the Vøring Basin offshore Norway. Input data for the model is the present-day well log or sedimentary
23 column with an Excel input file and includes rock parameters such as thermal conductivity, total organic
24 carbon (TOC) content, porosity, and latent heats. The model accounts for sedimentation and burial
25 based on a rate calculated by the sedimentary layer thickness and age. Erosion of the sedimentary
26 column is also included to account for realistic basin evolution. Multiple sills can be emplaced within the
27 system with varying ages. The emplacement of a sill occurs instantaneously. The model can be applied

28 to volcanic sedimentary basins occurring globally. The model output includes the thermal evolution of
29 the sedimentary column through time, and the changes that take place following sill emplacement such
30 as TOC changes, thermal maturity, and the amount of organic and carbonate-derived CO₂. The TOC and
31 vitrinite results can be readily benchmarked within the tool to present-day values measured within the
32 sedimentary column. This allows the user to determine the conditions required to obtain results that
33 match observables and leads to a better understanding of metamorphic processes in sedimentary
34 basins.

35

36 **1 Introduction**

37 Volcanic processes can strongly influence the development of sedimentary basins associated with
38 continental margins. Magmatic bodies such as dikes and sills have a major impact on the thermal
39 evolution of these sedimentary basins. The short-term effects of igneous intrusions include deformation
40 and uplift of the intruded sediments, heating of the host rock, mineral reactions, generation of
41 petroleum, boiling of pore fluids and possible hydrothermal venting (Jamtveit et al., 2004; Malthe-
42 Sorensen et al., 2004; Svensen et al., 2004; Wang et al., 2012b). Long-term effects include focused fluid
43 flow, migration of hydrothermal and petroleum products, formation of mechanically strong dolerite and
44 hornfels in the contact aureole and differential compaction (Iyer et al., 2013; Iyer et al., 2017; Kjoberg et
45 al., 2017; Planke et al., 2005). This is of particular importance to understanding the carbon cycle, as
46 thermal stresses, besides those associated with burial, encountered by organic matter in immature
47 source rocks will determine the ultimate production and fate of the CO₂ and CH₄ generated. Vent
48 structures are intimately associated with sill intrusions in sedimentary basins globally and are thought to
49 have been formed contemporaneously due to overpressure generated by pore-fluid boiling gas
50 generation during thermogenic breakdown of kerogen (Aarnes et al., 2015; Iyer et al., 2017; Jamtveit et
51 al., 2004). Methane and other gases generated during this process may have driven catastrophic climate
52 change in the geological past (Svensen and Jamtveit, 2010; Svensen et al., 2009). Magmatic intrusions
53 are also of particular interest for hydrocarbon prospectivity and can impact petroleum systems in
54 positive and negative ways (Archer et al., 2005; Monreal et al., 2009; Peace et al., 2017). High
55 temperatures in the thermal aureole around such intrusions may induce maturation and hydrocarbon
56 generation in immature, shallow strata that may have not been productive under normal burial. On the
57 other hand, pre-emptive maturation of hydrocarbons around an intrusion may result in loss of
58 hydrocarbons if a suitable reservoir has not yet formed. Additionally, pre-existing oil in a reservoir may

59 crack to gas in the vicinity of magmatic intrusions resulting in degradation of a potential prospect. In
60 order to understand these problems, numerical models are widely used to reconstruct the thermal
61 history of a basin where only a few of these parameters are known.

62 A number of analytical and numerical models have been developed that study the thermal effects of
63 igneous intrusions dating back to the early- and mid-1900's (Jaeger, 1964; Jaeger, 1957, 1959; Lovering,
64 1935). Subsequent 1D and 2D models added additional complexity to the models by the addition of
65 emplacement mechanisms and timing, source rock maturation, hydrocarbon generation, latent heats of
66 devolatilization and maturation, fluid processes and overpressure generation (Aarnes et al., 2011a;
67 Fjeldskaar et al., 2008; Galushkin, 1997; Iyer et al., 2017; Monreal et al., 2009; Wang, 2013; Wang, 2012;
68 Wang et al., 2010; Wang and Song, 2012; Wang et al., 2012a). Contact metamorphic processes are well
69 understood (e.g. (Aarnes et al., 2010; Jamtveit et al., 1992; Tracy and Frost, 1991)), but many published
70 papers do not take into account the basin history or the variations in contact aureole thickness that arise
71 from the type of measuring method that has been used. In general, the contact metamorphic effects
72 depend on 1) sill thickness (note that dikes cannot be directly compared with sills), 2) sill emplacement
73 temperature, 3) thermal gradient and emplacement depth (i.e. temperature and background
74 maturation), 4) emplacement history (instantaneous versus prolonged magma flow), 5) host rock
75 composition and characteristics (such as thermal conductivity, organic carbon content, porosity,
76 permeability) and 6) conductive versus advective cooling (e.g. (Aarnes et al., 2010; Galushkin, 1997; Iyer
77 et al., 2013; Iyer et al., 2017; Jaeger, 1964; Lovering, 1935; Wang, 2012)). In addition, the contact
78 aureole width depends on how aureoles are studied and measured. The aureole thickness depends on
79 the proxy used, including sonic velocity, density, mineralogy and mineral properties, magnetic
80 susceptibility, total organic carbon content, vitrinite reflectivity, color, porosity, or organic geochemistry.
81 Note that these aureole thickness proxies will not necessarily give the same result. Finally, the aureole
82 thickness also depends on the proximity to other sills emplaced at the same time (see Aarnes et al.
83 (2011b) for a quantification).

84 In this paper we present a generic 1D thermal model, SILLi, which can be applied to studying the thermal
85 effects of sill intrusions in sedimentary basins globally. The motivation behind the model and manuscript
86 is to make a standardized numerical toolkit openly available that can be widely used by scientists with
87 varying backgrounds to test the effect of magmatic bodies in a wide variety of settings using readily
88 available data such as standard well logs and field measurements. The model incorporates relevant
89 processes associated with heat transfer from magmatic intrusions such as latent heat effects,

90 decarbonation reactions and organic matter maturation and also accounts for background maturation
91 and erosion by systematically reconstructing the entire present-day sedimentary column from the input
92 data. Lastly, the model results can be easily compared to the two most widely used aureole proxies in
93 sedimentary rocks, vitrinite reflectance (VR) and total organic carbon (TOC) data.

94

95 **2 Model Input**

96 The one dimensional, Finite Element Method (FEM) model numerically recreates the thermal effects of
97 sill emplacement in a sedimentary column. The model is written using MATLAB and requires version
98 2014b or higher to run. The model input is specified in an Excel (*.xls) file and is read by the Matlab file,
99 SILLi.m. The user also specifies the model resolution with the igneous intrusions and sedimentary layers
100 by giving the minimum spacing (m) or the minimum number of points in the Matlab file. The measure
101 that produces the highest resolution is used. The Excel file is composed of seven tabs outlined below. If
102 a previously calculated output file is available for the input file, the program prompts the user to choose
103 between loading the output file for further analysis and performing a new calculation which overwrites
104 the existing file.

105 For correct model use, the geological input needs to be based on either a borehole (with horizontal
106 stratigraphy) or an outcrop that is converted into a pseudo-borehole. If the case study is outcrop-based,
107 a pseudo-borehole stratigraphy should be constructed including the regional basin stratigraphy. Note
108 that sedimentary rocks present at higher stratigraphic levels elsewhere in the basin should be added to
109 the erosion history of the basin. Moreover, the sills (and samples) should be rotated back to horizontal if
110 the stratigraphy was tilted post sill emplacement. Using TOC and VR data from sedimentary rocks
111 outside the immediate contact aureoles will improve the model calibration.

112

113 **2.1 Fluid**

114 This tab contains four columns describing the fluid name, its density (kg/m^3), heat capacity (J/kg/K) and
115 thermal conductivity (W/m/K).

116

117 **2.2 Lithology**

118 This tab contains the data required for the model to build the present-day sedimentary column. The
119 various columns detail the name of the sedimentary layer (character only) and various material
120 properties such as density (kg/m^3), heat capacity (J/kg/K), porosity (fraction), thermal conductivity
121 (W/m/K), initial TOC content (wt%) and latent heats of organic maturation and dehydration (kJ/kg).
122 Information regarding the kind of carbonate contained in the sedimentary layer can be given in the last
123 column if decarbonation reactions are considered. The mineral constitution of the carbonate can be
124 chosen as marl (1), dolomite (2) or dolomite/evaporite mix (3). A zero (0) is entered in this column if
125 decarbonation reactions are not required. The lithology tab also contains columns where the present-
126 day top depth (m) and age (Ma) of each layer can be given which determine the depositional sequence
127 and sedimentation rate for the layer (see Section 3.1). Note that the ages of the sedimentary must be
128 unique. A hypothetical basement is added 10 m below the deepest sedimentary layer top depth.

129

130 **2.3 Erosion**

131 This tab is similar to the lithology tab and contains information on eroded layers. Additional columns in
132 this tab contain information regarding the erosion timing (Ma) and the thickness of the eroded layer
133 (m). Note that the top depth of the eroded layer must coincide with the top of a sedimentary layer in
134 the lithology tab. If part of sedimentary layer is indeed eroded before deposition continues (i.e. the
135 eroded layer lay inside a deposited layer), the layer needs to be considered as unique layers separated
136 by the eroded layer. Multiple eroded layers can have the same top depths provided that older layers
137 with the same top depth are eroded first. Similarly, eroded layers have to be eroded first prior to
138 deposition of younger layers. The ages of the eroded layers cannot coincide with other layers.

139

140 **2.4 Sills**

141 This tab contains information necessary for the emplacement of sill intrusions. The top depth (m) and
142 thickness (m) of the sill constrain the geometry of the intrusion. Additional information includes the
143 time of emplacement (Ma), emplacement temperature ($^{\circ}\text{C}$), melt and solid densities (kg/m^3), melt and
144 solid heat capacities (J/kg/K), thermal conductivity (W/m/K), solidus and liquidus temperatures of the
145 magma ($^{\circ}\text{C}$) and the latent heat of crystallization (kJ/kg). The emplacement of the intrusion is assumed
146 to be instantaneous. Note that the top depth of the sill cannot be the same as the top depth of a

147 sedimentary layer. On the same note, the top depth of a sedimentary layer cannot be inside a sill
148 intrusion. Emplacement ages cannot exactly coincide with layer ages.

149

150 **2.5 Temperature Data**

151 This tab contains temperature data (°C) vs. depth (m) for the sedimentary column. The data in this tab is
152 used to construct a geothermal gradient by using the best linear fit and therefore needs to contain at
153 least two data points. Additionally, the first data point must coincide with the column top describing the
154 surface temperature.

155

156 **2.6 Vitrinite Data (Optional)**

157 This tab contains present day vitrinite reflectance data presented in depth (m) and VR values (%Ro).
158 Standard deviation of the values when available can be included. This data is used for comparison of the
159 modelled VR values to observations. This tab can be left blank if no measured information is available.

160

161 **2.7 TOC Data (Optional)**

162 This tab contains present day TOC content data (wt%) vs. depth (m) measured in the sedimentary
163 column which is used to compare to the model results. This tab can be left blank if no measured
164 information is available.

165

166 **3 Method**

167 **3.1 Sediment Deposition and Erosion**

168 Each sedimentary layer, including the eroded layers, is deposited sequentially in time based on the
169 depositional age. The rate of sedimentation for each layer is determined by the thickness of the layer
170 and the difference in time between its top age and that of the layer deposited before it. Erosional layers
171 in the sedimentary column are deposited in the same way as other layers. Erosion of the entire layer
172 occurs within a single step at the specified erosion age. The temperature boundary conditions are
173 accordingly adjusted for the height of the new sedimentary column. Note that the bottom boundary is

174 extended to 5 times the thickness of the bottommost sill if that sill is close to or at the bottom boundary
 175 (hypothetical basement) in order to remove boundary effects and resolve aureole processes that are
 176 mostly limited to less than 4 times the sill thickness (Aarnes et al., 2010).

177

178 **3.2 Thermal Diffusion**

179 The thermal solver computes the temperature within the deposited sedimentary column by applying
 180 fixed temperatures at the top and bottom at every step which are calculated from the prescribed
 181 geotherm (see Section 2.5) and the energy diffusion equation,

$$182 \quad \left[\phi \rho_f c_{pf} + (1 - \phi) \rho_r c_{peff} \right] \frac{\partial T}{\partial t} = \nabla \cdot (\kappa_{eff} \nabla T) \quad (1)$$

183 κ_{eff} is the bulk thermal conductivity that includes the rock and fluid contributions as a geometric mean
 184 (Hantschel and Kauerauf, 2009):

$$185 \quad \kappa_{eff} = \kappa_r^{(1-\phi)} \kappa_f^\phi \quad (2)$$

186 Table 1 contains the definitions of all the notations used in the manuscript. The effective rock heat
 187 capacity accounts for the latent heat of fusion in the crystallizing parts of the sill between the solidus (T_S)
 188 and liquidus (T_L) temperature of the magma (e.g. (Galushkin, 1997))

$$189 \quad c_{peff} = c_{pm} \left[1 + \frac{L_c}{(T_L - T_S) c_{pm}} \right] \text{ if } [T_S < T < T_L] \quad (3)$$

$$c_{peff} = c_{pr} \quad \text{if } [T_S > T]$$

190 Sills are emplaced instantaneously at the specified time and temperature within the sedimentary
 191 column. The emplacement of multiple sills in the same step is possible. The time-steps used for thermal
 192 diffusion after sill emplacement are automatically calculated based on the sill thickness and the
 193 characteristic time required for thermal diffusion. The time step is initially small in order to accurately
 194 resolve the thermal evolution of the contact aureole around the sill and is gradually increased once the
 195 energy released by the cooling sill is dissipated.

196 Dehydration reactions in the host rock are implemented by modifying the thermal diffusion equation
 197 when temperatures of the sediments increase within a certain range (Galushkin, 1997; Wang, 2012)

198

$$\left[\phi \rho_f c_{pf} + (1 - \phi) \rho_r c_{peff} \right] \frac{\partial T}{\partial t} = \nabla \cdot (\kappa \nabla T) - H \quad (4)$$

199

$$H = \frac{(1 - \phi) \rho_r L_d}{T_{d1} - T_{d2}} \frac{\partial T}{\partial t} \quad (5)$$

Symbol	Description	Units
<i>A</i>	Frequency factor	s ⁻¹
<i>C_{peff}</i>	Effective rock heat capacity	J kg ⁻¹ K ⁻¹
<i>C_{pf}</i>	Fluid heat capacity	J kg ⁻¹ K ⁻¹
<i>C_{pr}</i>	Rock heat capacity	J kg ⁻¹ K ⁻¹
<i>E</i>	Activation energy	KJ mol ⁻¹
<i>f</i>	Stoichiometric factor	
<i>F</i>	Reaction extent	
<i>g</i>	Gravitational acceleration	m s ⁻²

ρ_r	Rock density	kg m^{-3}

200 *Table 1. Definition of symbols used in the model.*

201

202 **3.3 Thermal Maturation of Organic Matter**

203 Vitrinite reflectance is a widely used indicator of thermal maturity and can be readily measured in the
 204 field. One of the most common methods used to calculate the thermal maturity of the source rock is the
 205 EASY%Ro method put forward by Sweeney and Burnham (1990). This model uses 20 parallel Arrhenius-
 206 type of first order reactions to describe the complex process of kerogen breakdown due to temperature
 207 increase. The reaction for the i^{th} component is given by

$$208 \quad \frac{dw_i}{dt} = -w_i A \exp\left[-\frac{E_i}{RT^t}\right] \quad (6)$$

209 where w_i is the amount of material for component i , E_i is the activation energy for the given reaction and
 210 T^t is time-dependent temperature.

211 The total amount of material reacted is obtained by summing up the individual reactions

$$212 \quad \frac{dw}{dt} = \sum_i \frac{dw_i}{dt} \quad (7)$$

213 The fraction of reactant converted is

$$214 \quad F = 1 - \frac{w}{w_0} = 1 - \sum_i f_i \left(\frac{w_i}{w_{0i}} \right) \quad (8)$$

215 from which the vitrinite reflectance can be readily calculated by

$$216 \quad \%Ro = \exp(-1.6 + 3.7F) \quad (9)$$

217 The amount of TOC that has reacted for any given time can be calculated by

218
$$\text{TOC}(t) = \text{TOC}_o F(t) \quad (10)$$

219 and the rate of organic matter degradation by

220
$$R_{om} = (1 - \phi) \rho_r \frac{\partial \text{TOC}}{\partial t} \quad (11)$$

221 The maximum amount of TOC that can be reacted by this method is 85% of the initial total. Note that in
 222 the inner part of the contact aureole close the sill, data shows that all of the organic matter has been
 223 reacted or removed (eg. LA1/68 in section 5.2.2). We assume that all of the hydrocarbons released
 224 during thermal degradation are converted into carbon dioxide. The amount of organic carbon dioxide
 225 generated (R_{CO_2}) for a time step is given by

226
$$R_{CO_2} = R_{om} m_{CO_2} \quad (12)$$

227 where m_{CO_2} is a stoichiometric conversion factor (3.67) to transform carbon into carbon dioxide. Note
 228 that metamorphism of sedimentary rocks will generate CH_4 (e.g., (Aarnes et al., 2010; Iyer et al., 2017)),
 229 but in our model the reacted carbon is recalculated to CO_2 . If needed, the CO_2 model output can be
 230 easily converted to either C or CH_4 .

231 The latent heat of organic maturation is accounted for in the energy equation

232
$$\left[\phi \rho_f c_{pf} + (1 - \phi) \rho_r c_{peff} \right] \frac{\partial T}{\partial t} = \nabla \cdot (\kappa \nabla T) - H - L_{om} R_{om} \quad (13)$$

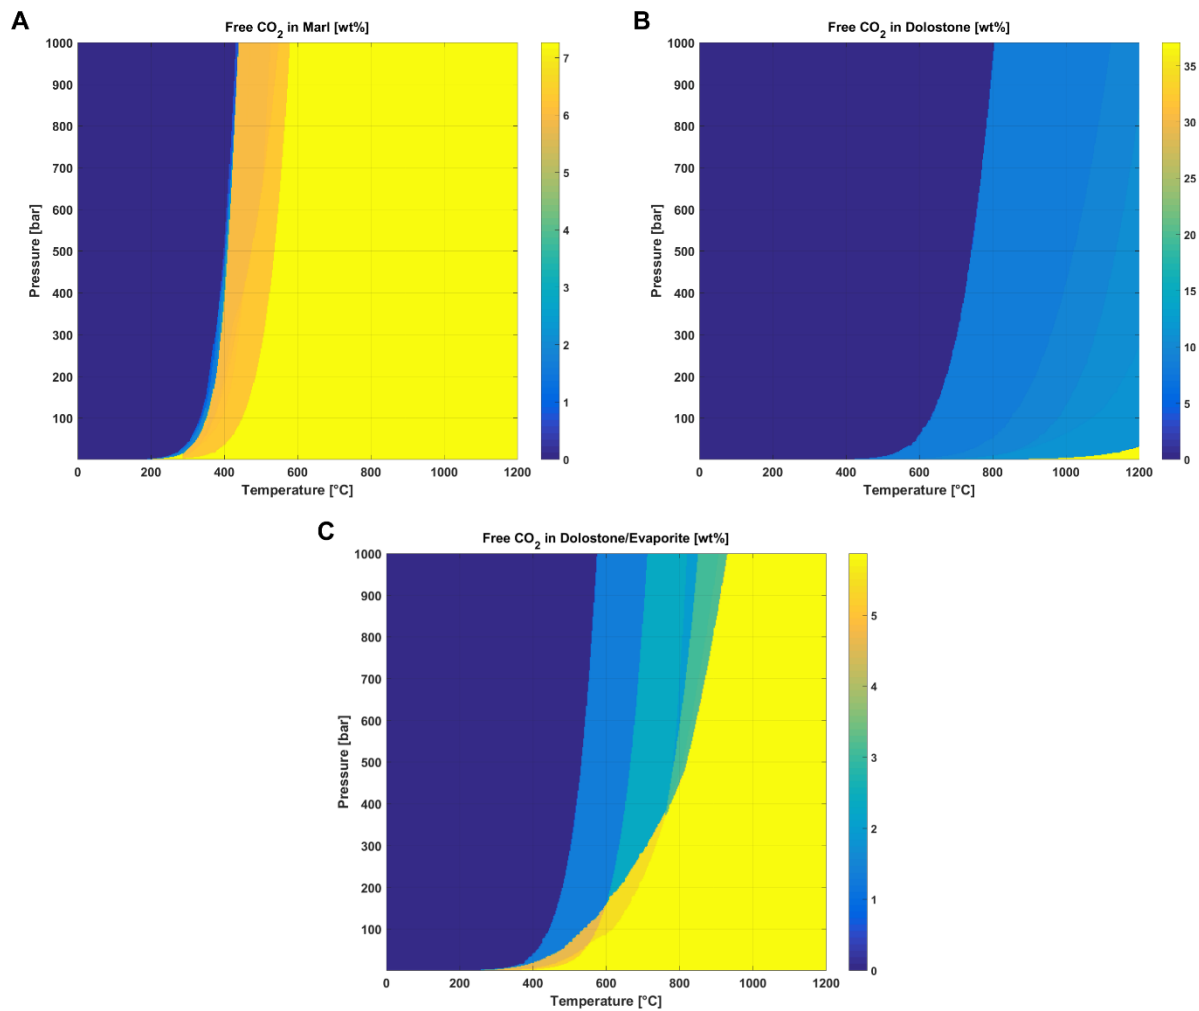

233

234 **3.4 Mineral Decarbonation**

235 Carbonate minerals undergo decarbonation reactions as they are heated to high temperatures. This
 236 results in mineral transformations and the release of inorganic carbon dioxide which may significantly
 237 add to the CO_2 budget associated with igneous intrusions. The amount of inorganic CO_2 liberated during
 238 metamorphic transformation over a range of temperature and fluid pressure for marl, dolomite and
 239 dolomite/evaporite mixture is pre-computed as a phase diagram using Perple_X (Connolly and Petriani,
 240 2002) (Figure 1). The model evaluates the total amount of inorganic CO_2 liberated by carbonate layers
 241 based on the temperature and pressure evolution of the layer through time within the phase diagrams.

242 Fluid pressure within the sedimentary column is calculated by integrating the rock density over depth in
243 addition to atmospheric pressure:

244
$$P_{H_2O} = P_{atm} + \int_{Z_{min}}^{Z_{max}} \rho_f \vec{g}$$
 (14)

245
246 *Figure 1. Phase diagrams generated by Perple_X showing the amounts of inorganic CO₂ liberated with*
247 *respect to temperature and pressure for marl (A), dolostone (B) and dolostone/evaporite (C).*

248

249 3.5 Model Mesh and Time-Stepping

250 The entire sedimentary column including the eroded layers and igneous intrusions is reconstructed and
251 the column nodes and elements for the FEM model are generated using the user-specified resolution.

252 The nodes are initially collapsed onto each other in depth. Each sedimentary node is assigned a time
253 during which it is expanded (or deposited) within the sedimentary column based on the layer age and its
254 thickness. All of the elements and nodes associated with each igneous intrusion are expanded
255 simultaneously during the corresponding emplacement time. Eroded layers are removed in a single time
256 step specified by the erosion age and the corresponding nodes are collapsed. In order to correctly
257 capture thermal diffusion across the large thermal gradient adjacent to a hot intrusion, the time step is
258 initially very small and exponentially increases during the heating period after sill emplacement and
259 before the next depositional event. The heating period of the sill, over which the exponential time sub-
260 stepping is used, is analytically determined from the characteristic diffusion time for the sill thickness
261 (Jaeger, 1959).

262

263 **3.6 Model Limitations**

- 264 • The model is one-dimensional and will therefore not resolve thermal effects that would require
265 a full 3D model.
- 266 • The model does not account for advective transport of heat through the system by fluids.
267 However, previous models have shown that this process would be dominant only in high
268 permeability systems or at the sill edges/tips in low permeability systems (Iyer et al., 2013; Iyer
269 et al., 2017). Therefore, the model presented in this manuscript works well for relatively low
270 permeability systems with shales, mudstone etc. and when the sedimentary column passes
271 through the sill interior away from the edges. Nevertheless, in some cases the effects of
272 hydrothermal activity may be visible where the thermal aureole is larger above than below the
273 sill and is recorded by vitrinite reflectance data (Galushkin, 1997; Wang and Manga, 2015). In
274 such cases, the user may use an enhanced thermal conductivity (up to 5 times the usual rock
275 conductivity) in the layer above the sill following the Nusselt number approach to account for
276 hydrothermal activity and match field data. Note that care should be taken to check if the same
277 effect can also be attributed to changes in other material properties or geological processes.
- 278 • The model does not account for other mineral reactions in the contact aureole besides
279 decarbonation of carbonates. The various mineral reactions possible in the contact aureole can
280 be implemented as an add-on module to the model if needed using the thermal evolution of the
281 sedimentary column obtained from the model. Similarly, correlation to other maturity

282 parameters such as mineralogical markers or biomarkers (e.g. Muirhead et al. (2017)) can be
283 performed by the user using the time-temperature evolution from the model if so desired.

- 284 • The model assumes that TOC conversion in all types of sedimentary rocks can be estimated by
285 using the EASY%Ro method with a maximum conversion value of 85%. Although, this is a good
286 first approximation, it cannot account for the complete loss of carbon in zones very close to the
287 sill-host rock interface which would result in an underestimation of the released gases (Svensen
288 et al., 2015). On the other hand, the provenance of the sedimentary rock can also significantly
289 affect how kerogen present in organic matter reacts to form hydrocarbons which may result in a
290 reduction in the amount of convertible organic matter due to the presence of inert kerogen (Iyer
291 et al., 2017; Pepper and Corvi, 1995).

292

293 **4 Model Output**

294 The model input and results are presented with the help of a GUI (Section 4.6). Model data are written
295 out as a single .mat (Matlab data) file in the same directory as the user-defined path for the input Excel
296 file and with the same filename. The file contains five 'struct' variables of which three contain input
297 information (rock, sill and welldata) and the other two contain model results (result and release). The
298 structure of the variables are described below.

299

300 **4.1 Struct Variable: rock**

301 This variable contains input information on the sedimentary layers in the column including the eroded
302 layers. The information is saved as variables given in Table 2 and is sorted according to their top depths.
303 Note that top depths are corrected for the eroded layers that are also included.

<u>Variable Name</u>	<u>Description</u>
Name	User-defined names of all the sedimentary layers in the column.
num	Total number of deposited sedimentary layers.
top	Top depth of the shallowest sedimentary layer.
bot	Top depth of the deepest sedimentary layer.
Tops	Top depths of sedimentary layers.
Ages	Ages of sedimentary layers.

Rho	Density of sedimentary layers.
Cp	Heat capacity of sedimentary layers.
Phi	Porosity of sedimentary layers.
K	Thermal conductivity of sedimentary layers.
Toc	TOC content of sedimentary layers.
Lm	Latent heat of maturation of sedimentary layers.
Ld	Latent heat of dehydration of sedimentary layers.
Carb	Carbonate layer identifier (0-3).
Ero_t	Erosion age of sedimentary layers (NaN if layer is not eroded).
Ero_thick	Eroded thickness of sedimentary layers (NaN if layer is not eroded).
Ero_tops	Top depths of the eroded layers only.

304 *Table 2. List of variables in 'rock' struct variable of the output file.*

305

306 **4.2 Struct Variable: sill**

307 This variable contains input information on sill intrusions in the column. The information is saved as
308 variables given in Table 3 and is sorted according to their top depths.

<u>Variable Name</u>	<u>Description</u>
num	Total number of sill intrusions.
Tops	Top depths of sill intrusions.
E_time	Emplacement ages of sill intrusions.
E_temp	Emplacement temperatures of sill intrusions.
Rhom	Melt density of sill intrusions.
Cpm	Melt heat capacity of sill intrusions.
Rhos	Solid density of sill intrusions.
Cps	Solid heat capacity of sill intrusions.
K	Thermal conductivity of sedimentary layers.
Sol	Solidus of melt in sill intrusions.
Liq	Liquidus of melt in sill intrusions.
Ld	Latent heat of crystallization of melt in sill intrusions.

309 *Table 3. List of variables in 'sill' struct variable of the output file.*

310

311 **4.3 Struct Variable: welldata**

312 This variable contains input information on measured TOC, VR and temperature data for the
313 sedimentary column. The information is saved as variables given in Table 4.

<u>Variable Name</u>	<u>Description</u>
TOC	Measured TOC data vs. depth.
VR	Measured VR data vs. depth.
T	Measured temperature data vs. depth.

314 *Table 4. List of variables in 'welldata' struct variable of the output file.*

315

316 **4.4 Struct Variable: result**

317 This variable contains the model results which are saved for every time step when applicable, i.e.
318 variables that change over time have rows corresponding to the element or node number (depending
319 on where they are defined) and columns corresponding to the time step number. The information is
320 saved as variables given in Table 5.

<u>Variable Name</u>	<u>Description (Rows x Columns)</u>
nel	Number of elements in the model (1 x 1)
nnod	Number of nodes in the model (1 x 1)
Gcoord_c	Depth of element centers (1 x no. of elements)
Ind	Internal nodal indexing of sedimentary layers and intrusions (no. of nodes x 1). Intrusions are negatively indexed.
Ind_nel	Internal element indexing of sedimentary layers and intrusions (no. of elements x 1). Intrusions are negatively indexed.
Ind_carb	Nodal indexing of carbonate layers (0-3) (no. of nodes x 1).
Gcoord	Depth of nodes (no. of nodes x no. of time steps).
Temp	Nodal temperature (no. of nodes x no. of time steps).
Pres	Nodal hydrostatic pressure (no. of nodes x no. of time steps).

Toc	Remaining Toc content at nodes (no. of nodes x no. of time steps).
CO2_org	Organic carbon dioxide generated at nodes (no. of nodes x no. of time steps).
Ro	VR at nodes (no. of nodes x no. of time steps).
Tmax	Maximum temperature experienced at nodes (no. of nodes x no. of time steps).
Active	Binary index of 'deposited/expanded' nodes (no. of nodes x no. of time steps).
CO2_release	Inorganic carbon dioxide generated at nodes (no. of nodes x no. of time steps).
Time	Year count for time step (no. of time steps x 1).

321 *Table 5. List of variables in 'result' struct variable of the output file.*

322

323 **4.5 Struct Variable: release**

324 This variable contains the amounts of CO₂ released for every time step normalized to rock volume. The
 325 information is saved as variables given in Table 6.

<u>Variable Name</u>	<u>Description (Rows x Columns)</u>
CO2_org	Organic carbon dioxide generated in elements normalized to rock volume (no. of elements x no. of time steps).
CO2_rel	Inorganic carbon dioxide generated in elements normalized to rock volume (no. of elements x no. of time steps).

326 *Table 6. List of variables in 'release' struct variable of the output file.*

327

328 **4.6 Output Graphical User Interface (GUI)**

329 The GUI presented during and after the model run contains three tabs containing graphical
 330 representations of the input data, time evolution of model results and CO₂ release through time. An
 331 explanation of the tabs is given below using a hypothetical test case consisting of a sedimentary column
 332 with two sill intrusions and three eroded layers.

333 **4.6.1 Input Tab**

334 The left-most subplot of the input tab contains the reconstructed sedimentary column where the layers
 335 are colored according to their depositional age ([http://www.stratigraphy.org/index.php/ics-chart-](http://www.stratigraphy.org/index.php/ics-chart-timescale)
 336 [timescale](http://www.stratigraphy.org/index.php/ics-chart-timescale)) (Figure 2). The sedimentary column also contains eroded layers (hatched) and sill intrusions
 337 (speckled). The name and depositional age of a layer can be found by right-clicking the layer. The other

338 subplots in the input tab contain information on the density, porosity, initial TOC content and thermal
339 conductivity of the sedimentary layers. The values of these variables are plotted at the corresponding
340 layer top depth.

341
342 *Figure 2. Snapshot of the input tab generated for a hypothetical sedimentary column with two sill*
343 *intrusions and three eroded layers. Right-clicking a layer in the sedimentary column provides the name*
344 *and depositional/erosional age of the layer.*

345 4.6.2 Results Tab

346 The results tab consists of the evolution of temperature, vitrinite reflectance, TOC content, maximum
347 temperature, hydrostatic pressure, inorganic and organic CO₂ release within the sedimentary column
348 over simulated time (Figure 3). The evolution of these variables can be played or stepped through using
349 the player controls in the top left corner. Alternatively, the user can jump directly to the desired
350 geological time by inputting it in the player control. Note that this results in the plot jumping to the
351 time-step nearest the desired time input. Regions containing sill intrusions are highlighted in gray. Users
352 can copy plot data at any time step by right-clicking the curve.

353

354 *Figure 3. Snapshot of the results tab generated for a hypothetical sedimentary column with two sill*
 355 *intrusions and three eroded layers. Right-clicking any curve allows the user to copy curve data.*

356 **4.6.3 Release Tab**

357 The release tab plots the cumulative and rates of release of organic and inorganic CO₂ due to heating of
 358 the sedimentary layer by sill intrusions (Figure 4). The cumulative and release rates are summed over
 359 the entire sedimentary column. The user can use the cumulative amount of gas released to easily
 360 upscale to basin scales by multiplying the value by the area affected by sill intrusions. Users can copy
 361 plot data at any time step by right-clicking the curve.

362

363 *Figure 4. Snapshot of the release tab generated for a hypothetical sedimentary column with two sill*
 364 *intrusions and three eroded layers. Right-clicking any curve allows the user to copy curve data.*

365

366 5 Examples

367 The examples below are provided with the code and are used to benchmark observations to model
 368 results.

369 5.1 Utgard High

370 The Utgard sill complex is part of the North Atlantic Igneous Province (NAIP) in the Vøring and Møre
 371 Basins, offshore Norway. This region underwent massive volcanic activity at the Paleocene-Eocene
 372 boundary around ~55 Ma (Aarnes et al., 2015). The Utgard High borehole 6607/5-2 was drilled through
 373 two sills emplaced in the Upper Cretaceous sedimentary layers. The drilled lithological column consists
 374 of nine layers with the oldest being deposited 100 Ma (NPD Factpages,
 375 <http://factpages.npd.no/factpages/>) (Figure 5). For simplicity, the material properties of the entire
 376 sedimentary column is set to constant values with the exception of TOC content. TOC content of the
 377 Paleocene and Upper Cretaceous sedimentary layers are set to an initial value of 0.6 and 1.5 wt%,
 378 respectively. Carbonate and erosional layers are not considered. The modelled sedimentary layers are

379 sequentially deposited at the sedimentation rate calculated from the layer top ages. The two sills are
380 emplaced simultaneously within the Nise and Kvitnos Formations at 55 Ma at a temperature of 1150°C.
381 Sedimentary rocks around the emplaced sills are progressively heated as the sills cool. The vitrinite
382 reflectance values increase and the TOC content reduced by thermally degrading organic matter to form
383 CO₂ (Figure 6). Sedimentation after sill emplacement results in further burial and extension to produce
384 the present-day sedimentary column. Vitrinite reflectance and TOC data from the Norwegian Petroleum
385 Directorate (NPD) and a previous study (Aarnes et al., 2015) are used to benchmark the model and
386 match very well with the modelled results (Figure 7). Further information about the geological and
387 model setting can be found in Aarnes et al. (2015) and the input file '1d_sill_input_utgard.xlsx'.

388

389 *Figure 5. Input tab for the Utgard High example.*

390

391 *Figure 6. Results tab 50 years after the emplacement of sills at 55 Ma for the Utgard High example.*

394

395 *Figure 7. Results tab at the end of simulation time for the Utgard High example. The present-day VR and*
396 *TOC values (circles) show a good match with the model results.*

397

398 **5.2 Karoo**

399 The Karoo Large igneous province was emplaced through the Karoo Basin in South Africa in the Early
400 Jurassic. The basin contains sills and dykes of varying thickness (Chevallier and Woodford, 1999; du Toit,
401 1920; Svensen et al., 2015; Walker and Poldervaart, 1949) , emplaced at about 182.6 Ma (Svensen et al.,
402 2012). The basin stratigraphy consists of the Upper Carboniferous to the Triassic Karoo Supergroup and
403 is divided in five groups (the Dwyka, Ecca, Beaufort, Stormberg and Drakensberg groups) with a
404 postulated maximum cumulative thickness of 12 km and a preserved maximum thickness of 5.5 km
405 (Tankard et al., 2009). The depositional environments of the sediments range from marine and glacial
406 (the Dwyka Group), marine to deltaic (the Ecca Group), to fluvial (the Beaufort Group) and finally eolian
407 (the Stormberg Group) (Catuneanu et al., 1998). The Karoo Basin is overlain by 1.65 km of preserved
408 volcanic rocks of the Drakensberg Group, consisting mainly of stacked basalt flows erupted in a
409 continental and dry environment (e.g., (Duncan et al., 1984)). Several recent studies have been devoted
410 to contact metamorphism of the organic-rich Ecca Group (Aarnes et al., 2011b; Moorcroft and
411 Tonnelier, 2016) and the possible consequences of thermogenic methane venting on the Early Jurassic
412 climate (Svensen et al., 2007; Svensen et al., 2015). Here we present two borehole cases from the
413 central (borehole KL1/78) and eastern (borehole LA1/68) parts of the basin previously studied and
414 modelled by Aarnes et al. (2011b) and Svensen et al. (2015), respectively. The details regarding the
415 relative timing of sill emplacement is poorly constrained and we thus use the same age for all sills. If the
416 sills are closely spaced, this will result in a higher maximum temperature in the sedimentary rocks
417 between the sills (cf. (Aarnes et al., 2011b)). For the erosion history of the Karoo Basin, we refer to
418 Braun et al. (2014) and a rapid Late Cretaceous erosion event.

419 **5.2.1 Karoo KL1/78**

420 The first example from the Karoo Basin is a short borehole with a length of 136 m that penetrates the
421 Tierberg, Whitehill and Prince Albert Formations. However, these Formations underlie a massive erosion
422 sequence consisting of 2.5 km of extrusives (Drakensberg Group) and 1.5 km of sediments (Stormberg
423 and Beaufort Groups) and are also included in the model. The borehole penetrates a single 15m thick sill
424 at a depth of 72m (Figure 8). The sill is emplaced within the Prince Albert Formation at 182.6 Ma at a

425 temperature of 1150°C. Initial average TOC data for the sedimentary layers away from the sill intrusion
 426 is not known but can be roughly estimated using present-day values, i.e. the TOC values will be higher
 427 than current values as TOC is thermally broken down close to the intrusion. The initial input TOC data is
 428 subsequently refined so that a better match of the model results to the observed data is obtained,
 429 thereby highlighting how the model can be used to constrain initial conditions within the sedimentary
 430 column (Figure 9). The importance of considering the entire basin history when constructing the model
 431 is also emphasized by the VR results. The values of the VR results unaffected by the sill would be much
 432 lower than the observed values if the eroded sequences are not considered. Addition of these layers to
 433 the model results in added burial than would be expected than by just using the 136 m deep borehole.
 434 This translates the VR curve laterally thereby better fitting the observed values (Figure 9). The final
 435 model shows a good fit of TOC and VR to present day values. Model input data can be found in
 436 '1d_sill_input_kl178.xlsx'.

437

438

439 *Figure 8. Input tab for KL1/78.*

440

441 *Figure 9. Results tab at the end of simulation time for KL1/78 shows a good match to present-day TOC*
 442 *and VR values.*

443

444 5.2.2 Karoo LA1/68

445 The second example from the Karoo Basin is a borehole with a length of 1711 m that penetrates the
 446 basin down to the basement (Svensen et al., 2015). Additional erosional sequence consisting mostly of
 447 the Drakensberg lavas and a minor section of the Stormberg Group is also added. The borehole
 448 penetrates multiple sills throughout the entire column with thicknesses ranging from 2 to 132m (Figure
 449 10). Initial average TOC data for the sedimentary layers is estimated from present-day values. Similar to
 450 the previous example, material properties are iteratively changed within realistic bounds to arrive at an
 451 initial setup that matches the final observations well (Figure 11). Model input data can be found in
 452 '1d_sill_input_la168.xlsx'.

453

454 *Figure 10. Input tab for LA1/68.*

455

456 *Figure 11. Results tab at the end of simulation time for LA1/68 shows a good match to present-day TOC*
 457 *and VR values.*

458

459 5.3 Intrusion into a Pluton

460 This example has been added to provide an instance where the user may be interested in modelling the
461 thermal aureole of an emplaced sill or dyke but without the effects associated with deposition of
462 sedimentary layers and the thermal evolution of a basin, e.g. emplacement within an igneous or
463 metamorphic rock. Here, we consider an emplacement of a 100m thick sill into a 1.2km thick igneous
464 body that has cooled to a uniform temperature of 30°C (Figure 12). The host rock is constructed by
465 defining a top and bottom layer with the same material properties and ages that are very close to each
466 other (the code does not allow for two layers with the exact same age). In this example the top and
467 bottom layers have ages of 10 and 10.0001 Ma, respectively, and the intrusion is emplaced at 1 Ma. A
468 constant temperature for the host rock is defined by assigning the same temperature, 30°C, to both
469 intervals in the temperature tab of the excel input file. Thus, the thermal evolution of the intrusion can
470 be investigated independent of burial effects of a sedimentary basin if so desired (Figure 13). Further
471 information about the model setting can be found in the input file '1d_sill_input_dyke.xlsx'.

472

473 Figure 12. Input tab for the Pluton example.

474

475 *Figure 13. Results tab at the end of simulation time for the pluton example. VR and TOC data are not*
 476 *present for this hypothetical case.*

477

478 6 Conclusions

- 479 • SILLi is a numerical model quantifies the thermal evolution of contact aureoles around sills
 480 emplaced in sedimentary basins. The model includes basin history (burial and erosion), thus
 481 providing background-maturation levels of organic matter and consequently more realistic gas
 482 production estimates.
- 483 • SILLi is a user-friendly tool that is written in Matlab and uses Excel for input data.
- 484 • The 1D tool allows for the quick quantification of the thermal effects of sill intrusions. The
 485 results can be, therefore, used to further constrain and test the initial conditions that may have
 486 been present within the lithological column that match present-day observations.
- 487 • Model output includes peak temperature profiles, post-metamorphic TOC content, vitrinite
 488 reflectivity, and the cumulative amount and rate of CO₂ generation. These values can be readily
 489 upscaled to basin scales if the sill extent is known. The amount of CO₂ can also be easily
 490 converted to other carbon-bearing gases such as CH₄.

- 491 • Our three case studies demonstrate a good fit between aureole data (TOC and vitrinite
492 reflectivity) and model output showing that the model can be successfully applied to basins in
493 various global settings.

494

495 **7 Code Availability and Software Requirements**

496 The source code with examples is archived on Zenodo (DOI: <https://doi.org/10.5281/zenodo.1035878>).

497 The Github repository will be regularly updated with improvements and fixes
498 (<https://github.com/khiyer/SILLi>). Matlab 2014b or higher is required to run the code and Microsoft
499 Excel or any equivalent software is required to edit .xls files.
