This paper proposed a new model that successfully simulates the whole process of debris flow, without artificial intervention on setting initiating features.

This novel proposal is very important because the identification of potential debris-flow hazard zones is important for debris-flow risk assessment. An ideal approach to achieve this is simulating the debris flow using physical model. Nevertheless, this type of methods often assumes debris-flow initiating locations, volumes and velocities, which leads to large uncertainties and can not represent the real debris flow.
