

Reply to comments from referee 1 “Interactive comment on “<sup>231</sup>Pa and <sup>230</sup>Th in the ocean model of the Community Earth System Model (CESM1.3)” by Sifan Gu and Zhengyu Liu”

We thank the reviewer for his/her time for constructing the comments.

In the following, we have addressed all comments, with the original review text underlined in italics and red.

*Comments: 1) The authors seem unaware of the recent paper by Rempfer et al (2017, EPSL) which describes in detail how Pa and Th are implemented in their 3D ocean model. Their description is more comprehensive and complete in the sense that an interested reader has all information available to carry out the model development in another model. This comprehensiveness is also a hallmark of the earlier paper by Siddall et al (2005, EPSL). The paper here, however, does not provide the detail this reviewer is expecting of a GSMD contribution. The paper needs to take the Rempfer study into consideration and describe carefully in which way the authors' approach is the same, or where it deviates, and why. In the latter case, all parameter values are to be given, as this is a contribution to GSMD (with emphasis on Development which means that a developer can take this paper and create a Pa, Th model component from this information). At the current stage, the paper does not provide this information.*

Thanks for pointing out the paper by Rempfer et al., (2017). We have made substantial changes describing how Pa and Th are implemented in our model and the difference between Rempfer et al., (2017). We add a short review on previous modeling efforts (Line 80-89) and the similarity and difference between our method and previous studies (Line 200-207). Eq. (3) is the conservation equation for Pa and Th, which is how Pa and Th calculated in the model. The calculations of Pa and Th are based on this equation. In section 2.3, we explicitly describe each term in Eq. (3) and the values of different parameters, which includes all the information for reproduce the model development in another model. Also, we add Table 1 and Table 2 to show the abbreviation and values of different parameters used in text.

*2) Comment 1) does not only apply to the model description only but also to the one example Gu and Liu show, the effect of a collapse of the AMOC on Pa and Th. Rempfer et al (2017) carried out a water hosing experiment and analysed in detail how changes in the Pa/Th ratio inform about circulation changes in the North Atlantic. A critical comparison of the present results with Rempfer et al. is missing.*

In the revised version, we compare our results with Rempfer et al. 2017. We get similar particulate Pa/Th response in North Atlantic (their Fig. 8 and our Fig. 12) and we add a discussion in the text (Line 423-444).

*3) The authors state on line 134 that their implementation is based on Siddall et al (2005). Does this mean that it is identical, i.e. all the parameter values are the same? If not, a Table with the parameter values would be needed for complete information. As*

46 *stated above, this would be a requirement fro GSMD; too many studies are published*  
47 *nowadays with incomplete information.*

48 Sorry we did not make this clear enough. Yes, the parameters in the implementation is  
49 the same as Siddall et al., (2005). Values of different parameters are given in the text  
50 when it first appears. To make it clearer, we add a table to summarize the parameters and  
51 variable in Table 1 and Table 2.

52  
53 *4) The text on lines 144ff does some forward referencing to the equations. This should be*  
54 *avoided. First set the context, then introduce the equations and describe every parameter*  
55 *and variable that occurs in these equations. This would ensure easier reading. For*  
56 *example, eq 4 shows many parameters whose values are not given. On line 167 the*  
57 *authors say that eq 4 can be derived from (1) and (2). This is not obvious from the*  
58 *formulations of (1) and (2). Rather eq 4 is a variant of eq 10 of Siddall et al (2005).*  
59 *Again more detail and clarity are needed here.*

60 Thanks for pointing out the problems in the equations. We have rearranged the context  
61 and the equations as suggested. We explicitly show how  $A_p^i$  can be calculated from Eq. 1  
62 and 2 (Eq. 4, 5 and 6).

63  
64 *5) A central point of this paper is the implementation of Pa and Th in abiotic and biotic*  
65 *formulations. In order to appreciate this, more description and analysis should be*  
66 *provided. For example, the prescribed and simulated particle fluxes in different ocean*  
67 *provinces should be shown and compared. It should be quantified how and where they*  
68 *differ in order to better understand the consequence of these choices for Pa and Th.*  
69 *Given the present level of information in the paper, one can be convinced that the*  
70 *agreement of the two approaches for the control simulation is satisfactory. However, in*  
71 *the transient experiments, differences are rather large depending on the location where*  
72 *the variations are analysed (Fig. 7). Without a more detailed description, the reader is*  
73 *unable to understand the differences. For example, it would be most useful in Fig. 2*  
74 *below the first row to add panels of the biotic simulation for direct comparison.*  
75 *Implicitly, this information is provided in the scatter plots e)-h), but it would be easier for*  
76 *the reader to see the spatial distribution for the concentrations of the four constituents*  
77 *next to one another and to compare abiotic with biotic this way.*

78 First of all, the term abiotic and biotic seems to be not appropriate since Pa and Th are  
79 not actually involved in the biological activity. We change the term to “p-fixed” and “p-  
80 coupled” which clearly indicates the difference between two versions.

81  
82 Thanks for suggesting ways to show that the p-fixed and p-coupled versions give almost  
83 identical results in CTRL. We follow this advice and show directly the results of these  
84 two versions in Fig. 2, 3 and 4. Clearly, readers can see that p-fixed and p-coupled are  
85 similar in CTRL.

86  
87 For the HOSING experiment, we also add Fig. 8 to show the differences in particle  
88 production during AMOC\_on and AMOC\_off, which will help the discussion about the  
89 p-fixed and p-coupled Pa/Th differences in HOSING.

8) The authors follow the approach of Siddall et al (2015) and Rempfer et al (2017) to compare their control simulation with observations. Information is incomplete here as to which data has been used for this comparison. A table in the paper or in the supplementary material summarizing which data has been used would be helpful.

Thanks for suggesting to use a table to show the data used. We have added Table 3 to show the references used in model data comparison. Most of the data are also used in Rempfer et al., (2017).

9) Further to 8) reference to the important effort of GEOTRACES is missing. GEOTRACES offers a wealth of relevant new data. They were used in Rempfer et al (2017) and should also be incorporated into this study for a better and more comprehensive comparison.

Thanks for pointing out available GEOTRACES data. We have included those in the observation (Table 3). We show model results along two GEOTRACES transects as in Rempfer et al., (2017) (Fig. 2 and 3) for direct comparison. Our results are similar as the case Re3d in Rempfer et al. (2017), which does not include boundary scavenging and sediment resuspensions.

10) Information is missing under what conditions Exp\_1 and Exp\_2 were run. Were these abiotic or biotic simulations? Also, this is not evident in Fig. 5.

Sensitivity experiment Exp 1 and Exp 2 are abiotic simulations for computational efficiency (Line 212-213). Exp1 and Exp2 are carried under the same forcing as CTRL (Line 221-222).

11) In Fig. 2b high values of Th\_d are noted in the Southern Ocean. This is in contrast to Siddall et al. (2005, their Fig.2) and should be discussed. Is this also occurring in the biotic simulations (see also comment 7. Might the opal fluxes be too high there?

Since the GEOTRACE transects are more appropriate for model data comparison, we replace the zonal mean figure with the GEOTRACE transects and move the zonal mean figure to the supplementary information (Fig. S3). The high values of Th\_d in the Southern Ocean around 60°S in the model is consistent observations (Fig. S3b) since observations of Th\_d from 60°S-55°S are much larger than Th\_d from 55°S-40°S. In addition, our model is in much higher resolution than Siddall et al., (2005). The maximum Th\_d locates at around 60°S, decreasing if further southward in our model. Similar pattern also appears in Siddall et al., (2005). Their Th\_d maximum is at around 55°S, decreasing southward (but only two grid available in their model).

12) Lines 237-240: This statement is not instructive, nor is it very useful. It is noted that the author have performed only one quite simple sensitivity experiment, and this is increasing or decreasing K which changes all partition coefficients simultaneously. This limited perspective does, of course, not shed too much light on this important question. At least some more thoughts by the authors should be offered here, if not some more pertinent sensitivity tests with their model.

Thanks for pointing this out. We have removed this part. The poor performance in simulating particulate Pa and Th is also in Siddall et al., (2005) and Dutay et al., (2009). Rempfer et al., (2017) only shows Pa\_p/Th\_p and does not show individual Pa\_p and

Th<sub>p</sub>. It's possible the performance is limited by our choice of modeling scheme since the process in controlling Pa and Th activities are essentially the same among our study, Siddall et al., (2005) and Dutay et al., (2009). Although individual Pa<sub>p</sub> and Th<sub>p</sub> do not agree well with the observations, the ratio of Pa<sub>p</sub>/Th<sub>p</sub> in our CTRL experiment show similar results as in Rempfer et al. (2017) and sediment Pa<sub>p</sub>/Th<sub>p</sub> distribution agrees with available observations. And the ratio of Pa/Th is what we are interested in.

*13) Section 4.3. Here, a deeper analysis is required, in particular a comparison with the recent paper of Rempfer et al (2017). They provide an interesting spatial consideration of correlation and Pa/Th-AMOC sensitivity in the North Atlantic Ocean in order to shed light on the controversy whether, and to what extent, Pa/Th changes reflect AMOC changes. The paper here would be able to make an important further contribution to this question, but this opportunity is missed. The authors may argue that this is a paper for GSMD, and hence addressing scientific questions is not the primary purpose. This reviewer might agree with this view if the necessary information for model developers. At this stage, unfortunately, neither is the case.*

Thanks for pointing out the interesting spatial dependence behavior of Pa/Th in the hosing experiment in Rempfer et al., 2017. Our model, with much higher resolution, shows similar spatial pattern as theirs (Fig. 12). We add discussion of this spatial dependence in Line 423-444. This spatial dependence is mainly caused by AMOC, since the pattern in p-fixed and p-coupled are similar.

*14) On line 307 the authors argue that the abiotic version captures the major features of the transient simulation. Considering Fig. 7c, d, e, f this statement seems overstating the agreement. Important differences in the transient signal are evident. This should be discussed and explained.*

We agree that there are many differences between p-fixed and p-coupled response to freshwater forcing. If we compare Fig. 10 b and d, in North Atlantic, the sediment Pa/Th overall show increase in both p-fixed and p-coupled (except opal maximum region). In Fig. 9, the transient evolution figure, if we neglect the initial drop in p-coupled (red), the long-term trend between p-coupled and p-fixed are the same. Therefore, over low productivity and long time scale, the p-fixed capture the major features of sediment Pa/Th change and suggest that AMOC change is dominant. But on short time scale and over high productivity region, p-coupled response behaves quite differently from p-fixed. We discuss the differences in the revised manuscript (Line 381-420).

*15) From Table 1 it is evident that dust input was not considered in these experiments, although this is not explicitly stated in the text. It would be important to inform the reader why this choice was made, or better, quantify the effect on the Pa and Th concentrations if dust input is included in the simulations.*

Thanks for the suggestions. Dust is not included in the calculation. We use the parameters used in the control experiment in Siddall et al., (2005), which the partition coefficient for dust is 0. They also did sensitivity experiment and find dust flux is unimportant for Pa/Th fractionation. We have modified Fig.1, Table 1 and text (line135-137) accordingly.

182 16) line 383-385. The authors seemed to copy this part from another of their GSMD  
183 papers.  
184 Sorry for the mistake in the code availability part. We have fixed the error.  
185  
186 17) Throughout the paper, the English should be carefully revisited, in particular in  
187 section 4.3. In that section, more paragraphs would ease the reading.  
188 Follow this suggestion, we re-write section 4.3. In the revised version, we first discuss the  
189 p-fixed sediment Pa/Th response in the Atlantic, which generally increase during  
190 AMOC\_off (Line 339-358) and the magnitude of increase is related to particle  
191 distribution (Line 359-370). Then we discuss the p-coupled response. The change in  
192 sediment Pa/Th between AMOC\_on and AMOC\_off in p-coupled are similar to p-fixed  
193 in most North Atlantic (Line 371-380), but there are differences especially on short time  
194 scale and over high productivity region (Line 381-420). At last, we discuss the change in  
195 particulate Pa/Th in North Atlantic and show the depth dependence of the change (Line  
196 423-444).  
197

Reply to comments from referee 2

We thank the reviewer for his/her time for constructing the comments.

In the following, we have addressed all comments, with the original review text underlined in italics and red.

*“The paper  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in the ocean model of the community Earth system model (CESM1.3)” by S. Gu and Z. Liu is presenting the implementation of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in their general circulation model. It is mainly following the procedure defined by previous work Siddall et al (2005) and Dutay et al (2009). The implementation of the tracers in the model is described and results are compared to observations. However some severe weaknesses are found in the manuscript. The comparison with observation is insufficient, it is strictly following the analysis performed by Siddall et al in 2009, while It now exists , thanks to the GEOTRACES project, new data set. Moreover, the paper do not only show the implementation of the tracer in the model and its validation, which is the scope of the GMD journal, It also propose the response to hosing experiments that is paleoclimate studies that are application that are not devoted to this journal, Climate of the past would be a more appropriate journal if this study was more correctly analysed. For all these reasons I propose to reject this paper from publication in GMD.”*

Thanks for pointing out the new data set provide by GEOTRACES. In our revised manuscript, we include this new data set. A recent study by Rempfer et al., (2017) shows  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in Bern3D model. We also compare our results with theirs.

The results in the hosing experiment is an example to show the advantages of our model. The interpretation of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  as a paleo proxy for reconstructing AMOC has been questioned because it will also be influenced by particle flux change. Our model includes two versions of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , which can help to detangle these two effects. The hosing experiment is an example to show that with these two versions of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , our model is able to help the interpretation of paleo  $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions. GMD encourage submissions with “tangible and potentially useful advance related to model development” (Editorial 1.1, Introduction) and we think the content in the hosing experiment fits this scope.

*“Specific comments: Page 4 section 2.2. The authors show particle flux surface horizontal distribution without concrete comparison with observation. This diagnostic is interesting but it is not sufficient for the proposed study. The model uses particle concentrations and results are strongly dependent to the quality of these fields. It now exist observations to validate the particle fields (Lam et al, 2015) that were not available for Siddall et al (2005) and Dutay et al (2009). A more detailed analysis of the vertical particle concentration distribution at large scale is required.”*

The particle fields used in this study is generated from the ecosystem module of the CESM, which has been validated extensively in previous studies (e.g. Doney et al., 2009; Long et al., 2013; Moore et al., 2002, 2004; Moore and Braucher, 2008). The export production is similar to satellite observations in both pattern and magnitude (Sarmiento

and Gruber 2006). Global average POC concentration is  $2.6 \times 10^{-6}$  kgC/m<sup>3</sup>; CaCO<sub>3</sub> is  $1.1 \times 10^{-6}$  kgC/m<sup>3</sup> and opal is  $3.9 \times 10^{-6}$  kgSi/m<sup>3</sup>, consistent with Rempfer et al., (2011). Therefore, the particle fields in CESM is more or less right, although regional discrepancies from observation may exist. We appreciate the reviewer's suggestion to validate the performance of the ecosystem module of the CESM with new data. But our focus of study is the Pa/Th in the model.

Also, we show the distribution of particle fields to help the discussion of sediment <sup>231</sup>Pa/<sup>230</sup>Th, which is influenced largely by particle distribution. Compare with Siddall et al., 2005, Dutay et al., 2009, and Rempfer et al., 2017, all models use particle fields generate from different models (but the general patterns are the same) but yields similar <sup>231</sup>Pa and <sup>230</sup>Th results.

*“Page 5 section 2.3 Abiotic and Biotic name for simulations are not appropriate. These names suggest that the tracers are subject to different processes while it is not the case. The two approaches are the same except that the particles fields are fixed in the Abiotic run. None biogeochemical process affects the tracer except adsorption and desorption onto particles, so the appellation Biotic run seems exaggerated. Line 162: No validation of particle fields is performed while it affect strongly the model results. Observations are now available (see for instance lam et al 2015)”*

Thanks for pointing out this inappropriate usage. We have renamed the version which is coupled to the ecosystem model as “p-coupled” and the version which uses prescribed particle fields as “p-fixed”.

*“Pages 7 and 8 section 4, results Definition and way of estimation of the residence time given for the tracers should be explained.”*

The residence time is calculated as the ratio of global average total isotope activity and the radioactive ingrowth of the isotope. The way of calculated is used in Rempfer et al., (2017) and Yu et al., (1996). We add this in the revised manuscript (line 248-249).

*“Comparison of Atlantic zonal averaged model results with observations is no more adequate. It is strictly following analysis performed by Siddall et al (2005) and Dutay et al (2009) a decade ago, but now many new observations are available in the different basins thanks to the GEOTRACES program. This validation is not appropriate any more. Discussion concerning the ratio <sup>231</sup>Pa/<sup>230</sup>Th is very poor. More detailed analysis must be given. For instance what causes low ratio in the north atlantics south of Grennland: convection?”*

With the new GEOTRACES data, we update the model data comparison with two GEOTRACES transects in the Atlantic (Fig.2 and 3). This is a more appropriate comparison than Atlantic zonal mean figure.

The large-scale feature of sediment <sup>231</sup>Pa/<sup>230</sup>Th is small value in North Atlantic and large value in the Southern Ocean discussed in line 282-293. Regionally, the distribution of

sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is controlled by particle distribution (especially opal) due to the particle flux effect (line 56-58). The low values south of Greenland at about 50°N is because of this particle flux effect (line 293-296). Opal production is larger in both south and north of this region. Therefore, the particle flux effect will transport  $^{231}\text{Pa}$  out of this region, resulting lower sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in this region and higher sediment  $^{231}\text{Pa}/^{230}\text{Th}$  north and south of this region.

*“Page10 and 11. This part is already an attempt to use the model development for scientific question. It is not the purpose of GMD papers. This part should be more deeply analysed and submitted to another more appropriate journal (eg climate of the past)”*

The purpose of implementing  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CESM is to provide a tool to better interpret sediment  $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions. The advance of our modelling study compared with previous studies is that we have two version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  to separate the circulation effect and particle effect, both of which will change in response to freshwater forcing. Section 4.3 is to examine this model feature and show that although circulation effect dominates sediment  $^{231}\text{Pa}/^{230}\text{Th}$  over low productivity regions in the North Atlantic and on long time scale, particle effect can be important over high productivity region and on short time scale. This part is an example to show the model advantage to detangle these two effects and therefore we think it is important to include this part to demonstrate our model advantage.

Reply to comments from referee 3

We thank the reviewer for his/her time for constructing the comments.

In the following, we have addressed all comments, with the original review text underlined in italics and red.

*“The main point of criticism I have here is their comparison to observational data, which I find is too nebulous and not supported by newer data. There is an obvious lack of consideration of recent papers. More recent studies would provide a much better basis for comparison and reality-checks of the model. The references for the observational data given in the MS are quite old holding mostly data obtained by the noisy counting-method resulting in large analytical uncertainties. Instead the model should be cross-checked with newer sedimentary and water column data. I don’t see much benefit from comparing “biotic” against “abiotic”  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  particle-fluxes (Fig. 2), as long as the absolute values have not been tested against new observational data. The authors urgently need to test the output of the model versus recent sedimentary data (e.g. (Böhm et al., 2015; Bradtmiller et al., 2014; Burckel et al., 2016; Henry et al., 2016; Hoffmann et al., 2013; Jonkers et al., 2015; Lippold et al., 2011; Lippold et al., 2016; Lippold et al., 2012; Luo et al., 2015; Negre et al., 2010; Roberts et al., 2014; Rutgers van der Loeff et al., 2016)), water data (e.g. (Deng et al., 2014; Hayes et al., 2014; Hayes et al., 2013; Hayes et al., 2015a; Hayes et al., 2015b; Kretschmer et al., 2011)) and most importantly other modelling studies (e.g. (Dutay et al., 2015; Lippold et al., 2011; Rempfer et al., 2017)).”*

Thanks for pointing recent available observations. We have updated our analysis with more complete data. The references for observations are listed in Table 3, which includes all the references used for model data comparison in Rempfer et al., (2017). Unfortunately, there is no intercalibrated dataset available.

In the revised manuscript, we replace the zonal mean figure with the GEOTRACE transects (Fig. 2 and 3), which seems to be more appropriate for direct model-data comparison. These two GEOTRACES transects are also shown in Rempfer et al. 2017. Our modelling scheme is essentially the same as Siddall et al., (2005) and the experiment Re3d in Rempfer et al., (2017), which does not include boundary scavenging and sediment resuspensions. Our results along the two GEOTRACES transects are similar to the Re3d in Rempfer et al., (2017). For dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , our model can simulate the right magnitude as in observations (Fig. 2 and 3) except in the abyssal. The larger values in the abyssal compared with observations is because we do not include boundary scavenging and sediment resuspensions in our model. As shown in Rempfer et al., (2017), if boundary scavenging and sediment resuspensions are added, the model performance in simulating the dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  will be much improved (their Fig. 2 and 3 top and bottom row). This is discussed in the revised manuscript (Line 255-263).

Rempfer et al., (2017) suggests that boundary scavenging and sediment resuspensions are unimportant for particulate  $^{231}\text{Pa}/^{230}\text{Th}$ . Our particulate  $^{231}\text{Pa}/^{230}\text{Th}$  (Fig. 2c and Fig. 3c) in the Atlantic show similar results as Rempfer et al., (2017). Most importantly, our sediment  $^{231}\text{Pa}/^{230}\text{Th}$  compares well with available observations (Fig. 4): low values in North Atlantic and high values in the Southern Ocean; high values in high productivity regions (Line 281-296).

In addition, we show side by side comparison between “abiotic” and “biotic” version in revised Fig. 2, 3 and 4 to directly show that the two versions give identical results in CTRL (Line 237-246). Although these two are similar in CTRL, they do vary differently in the HOSING experiment. Therefore, we find it may be clearer for readers to directly see the comparison between the two version in both CTRL and HOSING.

*“I find the terms “biotic 231Pa/230Th” and “abiotic 231Pa/230Th” quite confusing. Since there is no biotic 231Pa and 230Th these terms should be used only to distinguish between the usage of particle fields in the model.”*

Thanks for pointing out this inappropriate usage. We have renamed the version which is coupled to the ecosystem model as “p-coupled” and the version which uses prescribed particle fields as “p-fixed” as suggested.

*“Given that (Rempfer et al., 2017) recently provided insights into an upgraded approach by (Siddall et al., 2005) and (Siddall et al., 2007), including a bio-geochemical-module in the model, I do not see much advance provided by the here presented MS. I did not find a reference to (Rempfer et al., 2017), maybe because this is a very recent publication, but I don't think the authors should neglect this paper in a new version.”*

Thanks for referring to Rempfer et al., (2017). We add comparison with their results in the revised manuscript. In CTRL, our water column dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  is similar as Re3d in Rempfer et al., (2017) which do not include boundary scavenging and sediment resuspensions. The particulate  $^{231}\text{Pa}/^{230}\text{Th}$  in the Atlantic is also similar to Rempfer et al., (2017). In the hosing experiment, our model produces the similar spatial dependence of particulate  $^{231}\text{Pa}/^{230}\text{Th}$  in the Atlantic (our Fig. 12 and their Fig.8). The text referring to Rempfer et al., 2017 are in line 86-89, 202-207, 255-263, 423-444.

*“Although I welcome very much the provision of the Fortran code the reader is left alone with the comparison between model and observations (Fig.3) without sufficient information about the values, observational error bars and references. The color code in Fig. 3 may hold some information about the water depths, but since (already) older publications demandingly have shown, that the correlation of 231Pa/230Th with water-depth seems to be a manifested pattern of AMOC in the 231Pa/230Th distribution (Burckel et al., 2016; Gherardi et al., 2009; Gherardi et al., 2010; Hoffmann et al., 2013; Luo et al., 2010; Luo et al., 2015) this feature is required to be reproduced by a meaningful model. But I'm not able to see this from the provided figures.”*

Thanks for pointing out the important depth dependence of  $^{231}\text{Pa}/^{230}\text{Th}$ . In our revised Fig. 2 and 3, particulate  $^{231}\text{Pa}/^{230}\text{Th}$  in the Atlantic transects are shown.  $^{231}\text{Pa}/^{230}\text{Th}$  increases with depth as suggested by previous studies (Line 277-280). We also show North Atlantic average particulate  $^{231}\text{Pa}/^{230}\text{Th}$  profile in Fig.12. We further discuss this depth dependence in the HOSING experiment (Line 423-444). Our results supports the argument that this depth dependence is caused by the lateral transport of  $^{231}\text{Pa}$  by ocean circulation (Gherardi et al., 2009; Lippold et al., 2011, 2012; Luo et al., 2010).

*“By the way, the diagrams are way too detailed (in terms of graphic resolution) demanding a lot of computer resources and slowing down even my reasonably new computer just by scrolling down.”*

Sorry the resolution of figure is too large. We have compress this figure in the revised manuscript.

*“The table for the K values (Table 1) needs to be accompanied by references, because these values vary within a wide range according to the studies by (Chase et al., 2002, 2004; Hayes et al., 2013; Hayes et al., 2015b; Kretschmer et al., 2011; Kretschmer et al., 2008; Luo et al., 1999, 2003, 2004) and others. I think, a well selected digest of values can be found at the new study by (Rempfer et al., 2017).”*

The K values used in our control experiment are the same as what used in Siddall et al., (2005), which is from Chase et al., (2002). We have added these references in the Table 2 (originally Table 1) caption in the revised manuscript.

*“Besides the shortcomings of the MS regarding the observational data, I also find patterns in the model output, which are not observed in reality to my knowledge. E.g. the appearance of a high opal/POC field in the NW-Atlantic. Further, I see an obvious mismatch of model and observations in Fig. 5, which is not explained.”*

The particle fields are produced by the marine ecosystem module in CESM. This ecosystem module is have been discussed in many previous studies (e.g. Doney et al., 2009; Long et al., 2013; Moore et al., 2002, 2004; Moore and Braucher, 2008) (Line 122-123). The general pattern globally is similar to the satellite observations (Sarmiento and Gruber 2006). For example, low production in subtropical gyre; high opal in the Southern Ocean. Regionally, the mismatch can be caused by many different aspects, such as modelling scheme, model resolution and biases in boundary conditions. How to improve the performance of the marine ecosystem module is beyond the scope this study.

The Fig. 6 (originally Fig. 5) shows the results of sensitivity experiments. The discussion is in line 303-310. The mismatch of model and observation is reasonable since we change the partition coefficients K in these two experiments. Take EXP\_1 for example, the simulated dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  (Fig. 6 and b) are much larger than observations because in EXP\_1, K is decreased from CTRL by a factor of 5. Smaller K means smaller sink for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , with the source kept the same, dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  will

increase. The mismatch of model and observations also suggest that K is in the correct magnitude in CTRL.

*“In summary, it is hard for me to see that the here presented model approach provides any new insights on the  $^{231}\text{Pa}/^{230}\text{Th}$  method. Due to the lack of information about the model-data comparison it is not possible to assess the quality of the model and the applied parameters. Consequently I suggest revising both the model runs and the MS thoroughly before publication can be considered.”*

In our revised manuscript, we compare our model results with new GEOTRACES data and also compare with the recent modelling study by Rempfer et al., (2017). Overall, our model can simulate the general features in water column  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  and sediment  $^{231}\text{Pa}/^{230}\text{Th}$ . Different from Rempfer et al., (2017), we have two versions of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ : p-fixed and p-coupled, which have the advantage to detangle the circulation effect and particle effect in controlling sediment  $^{231}\text{Pa}/^{230}\text{Th}$ . In our hosing experiment, these two version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  do show different responses. Therefore, our model is a useful tool to improve the interpretations of  $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions.

 482 Abstract  
 483 Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio is emerging as an important proxy for  
 484 deep ocean circulation in the past. In order to allow for a direct model-data  
 485 comparison and to improve our understanding of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity  
 486 ratio, we implement  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in the ocean component of the Community  
 487 Earth System Model (CESM). In addition to the p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  that is fully  
 488 coupled with the active marine ecosystem module, another form of p-fixed  $^{231}\text{Pa}$  and  
 489  $^{230}\text{Th}$  have also been implemented with prescribed particle flux fields of the present  
 490 climate. The comparison of the two forms of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  helps to isolate the  
 491 influence of the particle fluxes from that of circulation. Under present day climate  
 492 forcing, our model is able to simulate water column  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity and  
 493 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in good agreement with available observations.  
 494 In addition, the p-coupled and p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratios behave  
 495 similarly over large areas of low productivity on long timescale to freshwater  
 496 forcing, but can differ substantially in some regions of high productivity and on  
 497 short timescale, indicating the importance of biological productivity in addition to  
 498 physical circulation. Therefore, our model provides a potentially powerful tool to  
 499 help our interpretation of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions and to improve our  
 500 understanding of past ocean circulation and climate changes.

**1. Introduction**

Sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio has been used as a proxy to reconstruct ocean circulation in the past (e.g. Yu et al. 1996; McManus et al. 2004; Gherardi et al. 2009).  $^{231}\text{Pa}$  (32.5 ka half-life) and  $^{230}\text{Th}$  (75.2 ka half-life) are produced at a constant rate approximately uniformly in the ocean by the  $\alpha$  decay of  $^{235}\text{U}$  and  $^{234}\text{U}$ , respectively, with a production activity ratio of 0.093 (Henderson and Anderson, 2003). Water column  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are subject to particle scavenging and transport to sediments (Bacon and Anderson, 1982; Nozaki et al., 1987). Differential scavenging efficiency results in different ocean residence time:  $^{231}\text{Pa}$  has a residence time of approximately 111 years and  $^{230}\text{Th}$  has a residence time of approximately 26 years (Yu et al., 1996). Longer residence time of  $^{231}\text{Pa}$  than  $^{230}\text{Th}$  makes  $^{231}\text{Pa}$  more subject to ocean transport and therefore in modern ocean about 45% of  $^{231}\text{Pa}$  produced in the Atlantic is transported to the Southern Ocean (Yu et al., 1996), resulting a lower than 0.093 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in the North Atlantic and higher than 0.093 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in the Southern Ocean.

The application of the principle above to interpret sediment  $^{231}\text{Pa}/^{230}\text{Th}$  as the strength of Atlantic Meridional Overturning Circulation (AMOC), however, can be complicated by other factors, leading to uncertainties in using  $^{231}\text{Pa}/^{230}\text{Th}$  as a proxy for paleocirculation (Keigwin and Boyle, 2008; Lippold et al., 2009; Scholten et al., 2008). In addition to ocean transport, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is also influenced by particle flux and composition (Chase et al., 2002; Geibert and Usbeck, 2004; Scholten et al., 2008; Siddall et al., 2007; Walter et al., 1997). The region of a higher particle flux tends to have a higher  $^{231}\text{Pa}/^{230}\text{Th}$  (Kumar et al., 1993; Yong Lao et al., 1992), which is referred to as the “particle flux effect” (Siddall et al., 2005). High particle flux in the water column in a region will favor the removal of isotopes into the sediment, which leads to more isotopes transported into this region due to the down-gradient diffusive flux into this region and subsequently more removal of isotopes into the sediment. Since  $^{231}\text{Pa}$  has a longer residence time, this effect is

Deleted: c  
Deleted: tracer

545 more prominent on  $^{231}\text{Pa}$  than on  $^{230}\text{Th}$  and therefore sediment  $^{231}\text{Pa}/^{230}\text{Th}$  will be  
 546 higher in high productivity regions. Also, opal is able to scavenge  $^{231}\text{Pa}$  much more  
 547 effectively than  $^{230}\text{Th}$ , leading to higher  $^{231}\text{Pa}/^{230}\text{Th}$  in high opal flux regions such as  
 548 the Southern Ocean (Chase et al., 2002). Moreover, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is  
 549 suggested to record circulation change only within 1000 m above the sediment,  
 550 instead of the whole water column, complicating the interpretation of sediment  
 551  $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions (Thomas et al., 2006). For example, sediment  
 552  $^{231}\text{Pa}/^{230}\text{Th}$  approaching 0.093 during Heinrich Stadial event 1(HS1) from the  
 553 subtropical North Atlantic is interpreted as the collapse of the Atlantic Meridional  
 554 Overturning Circulation (AMOC) (McManus et al., 2004). If sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
 555 only records deepest water mass, it is possible that during HS1, AMOC shoals, as  
 556 opposed to fully collapse, yet an increase of deep water imported from the Southern  
 557 Ocean featuring high  $^{231}\text{Pa}/^{230}\text{Th}$  can increase the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  approaching  
 558 the production ratio (0.093) (Thomas et al., 2006). All these suggest the importance  
 559 of incorporating  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  into climate models for a direct model-data  
 560 comparison for a thorough understanding of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  as well as past  
 561 ocean circulation.

562  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  have been simulated in previous modeling studies (Dutay et  
 563 al., 2009; Luo et al., 2010; Marchal et al., 2000; Rempfer et al., 2017; Siddall et al.,  
 564 2005). Marchal et al., (2000) simulates  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in a zonally averaged  
 565 circulation model, using the reversible scavenging model of Bacon and Anderson,  
 566 (1982). One step further, Siddall et al. (2005) extends Marchal et al., (2000) by  
 567 including particle dissolution with prescribed particle export production in a 3-D  
 568 circulation model. Rempfer et al., (2017) further couples  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  with active  
 569 biogeochemical model and includes boundary scavenging and sediment  
 570 resuspensions to improve model performance in simulating water column  $^{231}\text{Pa}$  and  
 571  $^{230}\text{Th}$  concentration. Here we follow previous studies to implement  $^{231}\text{Pa}$  and  $^{230}\text{Th}$   
 572 into the Community Earth System Model (CESM). Our model  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are  
 573 coupled with active marine ecosystem model ("p-coupled") and therefore can be  
 574 used to study the impact of ecosystem change on  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  directly. To help to  
 575 understand the influence of the particle flux, we have also implemented a "p-fixed"

version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , for which the particle fluxes are fixed at prescribed values. By comparing the p-fixed  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  with the p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , we will be able to separate the effect of circulation change from particle field change. In addition, the p-fixed  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can be run without the marine ecosystem module, reducing computational cost by a factor of 3 in the ocean-alone model simulation and therefore making it a computationally efficient tracer for sensitivity studies.

This paper describes the details of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CESM and serves as a reference for future studies using this tracer module. In section 2, we describe the model and the implementation of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . In sections 3, we describe the experimental design. We will finally compare simulated  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  fields with observations, show model sensitivities on the parameter and also sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio response to freshwater forcing in Section 4.

## 2. Model Description

### 2.1 Physical Ocean Model

We implement  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in the ocean model (Parallel Ocean Program version 2, POP2) (Danabasoglu et al., 2012) of CESM (Hurrell et al., 2013). CESM is a state-of-the-art coupled climate model and studies describing model components and analyzing results can be found in a special collection in Journal of Climate (<http://journals.ametsoc.org/topic/ccsm4-cesm1>). We run the ocean-alone model, which is coupled to data atmosphere, land, ice and river runoff under the normal year forcing of CORE-II data (Large and Yeager, 2008), using the low-resolution version of POP2 with a nominal  $3^\circ$  horizontal resolution and 60 vertical layers.

### 2.2 Biogeochemical component (BGC)

CESM has incorporated a marine ecosystem module that simulates biological variables (Moore et al., 2013). The marine ecosystem module has been validated against present day observations extensively (e.g. Doney et al., 2009; Long et al., 2013; Moore et al., 2002, 2004; Moore and Braucher, 2008). The implementation of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  requires particle fields:  $\text{CaCO}_3$ , opal and particulate organic carbon

Deleted: abiotic

Deleted: biotic

Deleted: abiotic

Deleted: . POP2

Formatted: Indent: First line: 0.5"

Deleted: four

Deleted: ,

(POC). These particle fields can be obtained from the ecosystem driver from the ecosystem module (Jahn et al., 2015). The ecosystem module simulates the particle fluxes in reasonable agreement with the present day observations. The pattern and magnitude of the annual mean particle fluxes (CaCO<sub>3</sub>, opal, POC) leaving the euphotic zone at 105m are similar to the satellite observations (Fig. 7.2.5 and 9.2.2 in Sarmiento and Gruber 2006) (Fig. 1 a~c): particle fluxes are higher in the high productivity regions such as high latitudes and equatorial Pacific; opal flux is high in the Southern Ocean. The remineralization scheme of particle is based on the ballast model of Armstrong et al., (2002). Detailed parameterizations for particle remineralization are documented in Moore et al., (2004) with temperature dependent remineralization length scales for POC and opal. We do not consider dust because it is suggested to be unimportant for <sup>231</sup>Pa and <sup>230</sup>Th fractionation (Chase et al., 2002; Siddall et al., 2005).

### 2.3 <sup>231</sup>Pa and <sup>230</sup>Th implementation

<sup>231</sup>Pa and <sup>230</sup>Th are produced from the  $\alpha$  decay of <sup>235</sup>U and <sup>234</sup>U uniformly everywhere at constant rate  $\beta^i$  ( $\beta^{\text{Pa}} = 2.33 \cdot 10^{-3}$  dpm m<sup>-3</sup> yr<sup>-1</sup>,  $\beta^{\text{Th}} = 2.52 \cdot 10^{-2}$  dpm m<sup>-3</sup> yr<sup>-1</sup>). <sup>231</sup>Pa and <sup>230</sup>Th are also subjective to radioactive decay with the decay constant of  $\lambda^i$  ( $\lambda^{\text{Pa}} = 2.13 \cdot 10^{-5}$  yr<sup>-1</sup>,  $\lambda^{\text{Th}} = 9.22 \cdot 10^{-6}$  yr<sup>-1</sup>).

Another important process contributes to <sup>231</sup>Pa and <sup>230</sup>Th activity is the reversible scavenging by sinking particles (Bacon and Anderson, 1982), which describes the adsorption of isotopes onto sinking particles and desorption after the dissolution of particles. This process transports <sup>231</sup>Pa and <sup>230</sup>Th downward and leads to a general increase of <sup>231</sup>Pa and <sup>230</sup>Th activity with depth. The reversible scavenging considers total isotope activity ( $A_t^i$ ) as two categories (Eq. (1)): dissolved isotopes ( $A_d^i$ ) and particulate isotopes ( $A_p^i$ ) (superscript i refers to <sup>231</sup>Pa and <sup>230</sup>Th) and  $A_p^i$  is the sum of the isotopes associated with different particle types ( $A_{j,p}^i$ ) (subscript j refers to different particle types: CaCO<sub>3</sub>, opal and POC):

$$A_t^i = A_d^i + A_p^i = A_d^i + \sum_j A_{j,p}^i \quad (1)$$

Deleted: and dust

Deleted: For ocean-alone experiments, atmospheric dust deposition to the surface ocean is prescribed from Luo et al. (2003) (Fig. 1d).

Deleted: as in

Deleted: Eq. (1)

672  
673 Dissolved and particulate isotopes are assumed to be in equilibrium, which is a  
674 reasonable assumption in the open ocean (Bacon and Anderson, 1982; Henderson et  
675 al., 1999; Moore and Hunter, 1985). The ratio between the particulate isotope  
676 activity and the dissolved isotope activity is set by a partition coefficient, K (Eq. (2)):

$$K_j^i = \frac{A_{j,p}^i}{A_d^i \cdot R_j} \quad (2)$$

677  
678 where  $R_j$  is the ratio of particle concentration ( $C_j$ ) to the density of seawater  
679 ( $1024.5 \text{ kg m}^{-3}$ ). Subscript j refers to different particle types ( $\text{CaCO}_3$ , opal and POC).  
680 Values of partition coefficient K used in our control simulation follows Chase et al.,  
681 2002 and Siddall et al., 2005 (Table 2).  
682

683 Particulate isotopes ( $A_p^i$ ) will be transported by sinking particles, which is  
684 described by  $w_s \frac{\partial A_p^i}{\partial z}$ , where  $w_s$  is sinking velocity. We don't differentiate between  
685 slow sinking small particles and rapid sinking large particles as in Dutay et al.,  
686 (2009) and consider all particles as slowly sinking small particles with sinking  
687 velocity of  $w_s = 1000 \text{ m yr}^{-1}$  (Arsouze et al., 2009; Dutay et al., 2009; Kriest, 2002) as  
688 in Rempfer et al., (2017) and Siddall et al., (2005). Any particulate isotopes ( $A_p^i$ ) at  
689 the ocean bottom layer are removed from the ocean as sediment, which is the sink  
690 for the isotope budget. Detailed vertical differentiation scheme to calculate this term  
691 in the model is in the supplementary material. The reversible scavenging scheme  
692 applied here is the same as the neodymium implementation in POP2 (Gu et al.,  
693 2017).

694 Particle fields used in the reversible scavenging can be either prescribed or  
695 simultaneously generated from the marine ecosystem module. Therefore, two forms  
696 of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are implemented in POP2: "p-fixed" and "p-coupled". P-fixed  $^{231}\text{Pa}$   
697 and  $^{230}\text{Th}$  use particle fluxes prescribed as annual mean particle fluxes generated  
698 from the marine ecosystem module under present day climate forcing (Fig.1). P-  
699 coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  use particle fluxes computed simultaneously from the

Deleted: which describes the adsorption of isotopes onto sinking particles and desorption after the dissolution of particles (Detailed vertical differentiation scheme to calculate this term in the model is in the supplementary material).

Moved up [1]: This process transports  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  downward and leads to a general increase of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity with depth.

Deleted: sizes

Moved up [2]: The reversible scavenging considers total isotope activity ( $A_t^i$ ) as two categories: dissolved isotopes ( $A_d^i$ ) and particulate isotopes ( $A_p^i$ ) (superscript i=1 and 2 refers to  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , respectively) as in Eq. (1) and assumes these two phases are in equilibrium, which is a reasonable assumption in the open ocean (Bacon and Anderson, 1982; Henderson et al., 1999; Moore and Hunter, 1985; Roy-Barman et al., 1996).

Moved up [3]: The ratio between the particulate isotope activity and the dissolved isotope activity is set by a partition coefficient, K (Eq. (2)), where  $C_j$  is the ratio of particle concentration to the density of seawater ( $1024.5 \text{ kg m}^{-3}$ ). Subscript j refers to different particle types ( $\text{CaCO}_3$ , opal, POC and dust).

marine ecosystem module. P-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can be turned on at the case build time and the p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  requires the ecosystem module to be turned on at the same time.

Therefore, the conservation equation for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activity can be written as

$$\frac{\partial A_t^i}{\partial t} = \beta^i - \lambda^i A_t^i - w_s \frac{\partial A_p^i}{\partial z} + \text{Transport} \quad (3)$$

where the total isotope activity is controlled by decay from U (first term), radioactive decay (second term), reversible scavenging (third term) and physical transport by the ocean model (fourth term, including advection, convection and diffusion).  $A_t^i$  can be calculated by combining Eq. (1) and Eq. (2):

$$\begin{aligned} A_t^i &= A_d^i + A_d^i \cdot (K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}) \\ &= A_d^i \cdot (1 + K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}) \end{aligned} \quad (4)$$

which leads to

$$A_d^i = \frac{A_t^i}{1 + K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}} \quad (5)$$

put this back to Eq.(1), we get

$$A_p^i = A_t^i \cdot \left(1 - \frac{1}{1 + K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal}}\right) \quad (6)$$

Comparing with previous studies of modeling  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , our p-fixed version is the same as Siddall et al., (2002), except that different prescribed particle fluxes are used. The p-coupled version allows coupling to biogeochemical module, which is similar in Rempfer et al., (2017), but we do not include boundary scavenging and sediment resuspensions as in Rempfer et al., (2017) because boundary scavenging and sediment resuspensions are suggested to be unimportant to influence the relationship between  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  and AMOC strength (Rempfer et al., 2017).

767 3. Experiments

768 We run a control experiment (CTRL) and two experiments with different  
769 partition coefficients to show model sensitivity to partition coefficient. We have  
770 both p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CTRL, but only p-fixed  $^{231}\text{Pa}$  and  $^{230}\text{Th}$   
771 in sensitivity experiments. Equilibrium partition coefficients for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  vary  
772 among different particle types and the magnitude of the partition coefficients for  
773 different particle types remains uncertain (Chase et al., 2002; Chase and Robert F,  
774 2004; Luo and Ku, 1999). Since the control experiment in Siddall et al., (2005) is  
775 able to simulate major features of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  distributions, we use the partition  
776 coefficients from the control experiment in Siddall et al., (2005) in our CTRL (Table  
777 2). Two sensitivity experiments are performed with decreased (EXP\_1) and  
778 increased (EXP\_2) partition coefficients by a factor of 5 (Table 2).

779 All the experiments are ocean-alone experiments with the normal year  
780 forcing by CORE-II data (Large and Yeager, 2008). The  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities are  
781 initiated from 0 in CTRL and are integrated for 2,000 model years until equilibrium  
782 is reached. EXP\_1 and EXP\_2 are initiated from 1,400 model year in CTRL and are  
783 integrated for another 800 model years to reach equilibrium.

784 Since sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in North Atlantic has been used to reflect the  
785 strength of AMOC, to test how sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in our model responds to the  
786 change of AMOC, we carried out a fresh water perturbation experiment (HOSING)  
787 with both p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . Starting from 2,000 model year of  
788 CTRL, a freshwater flux of 1 Sv is imposed over the North Atlantic region of  
789  $50^\circ\text{N}\sim 70^\circ\text{N}$  and the experiment is integrated for 1400 model years until both p-  
790 fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio have reached quasi-equilibrium. The  
791 partition coefficients used in HOSING are the same as in CTRL.

792

793 4. Results

794 4.1 Control Experiment

795 P-fixed and p-coupled version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CTRL show identical  
796 results (Fig. 2-4). P-fixed and p-coupled dissolved and particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in  
797 CTRL are highly correlated with each other, with correlations larger than 0.995 and

816 regression coefficients are all near 1.0 ( $R^2 > 0.995$ ). The correlation coefficient  
 817 between **p-fixed** and **p-coupled** sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratios in CTRL is 0.99  
 818 and the regression coefficient is 0.9 ( $R^2 = 0.98$ ) (Fig. 4a). This is expected because the  
 819 particle fields used in **p-fixed** version are the climatology of the particle fields used  
 820 in the **p-coupled** version. Therefore, under the same climate forcing, **p-fixed** and **p-**  
 821 **coupled** version of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  should be very similar. For the discussion of  
 822 results in CTRL below, we only discuss the **p-fixed**  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ .

823 The residence time of both  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  in CTRL are comparable with  
 824 observations. **The residence time is calculated as the ratio of global average total**  
 825 **isotope activity and the radioactive ingrowth of the isotope.** Residence time in CTRL  
 826 is 118 yr for  $^{231}\text{Pa}$  and 33 yr for  $^{230}\text{Th}$  (Table 2), which are of the same magnitude as  
 827 111 yr for  $^{231}\text{Pa}$  and 26 yr for  $^{230}\text{Th}$  in observation (Yu et al., 1996).

828 CTRL can simulate the general features of **dissolved** water column  $^{231}\text{Pa}$  and  
 829  $^{230}\text{Th}$  activities. **Dissolved**  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities increase with depth in CTRL, as  
 830 shown in **two GEOTRACES transects (Deng et al., 2014; Hayes et al., 2015) in the**  
 831 **Atlantic (Fig. 2 and 3).** The dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities in CTRL are also at  
 832 the same order of magnitude as in observations, **in the most of the ocean, except that**  
 833 **simulated values are larger than observations in abyssal, which is also the case in**  
 834 Siddall et al., (2005) and Rempfer et al., (2017) (their Fig. 2 and 3, experiment  
 835 Re3d). **Our model is unable to simulate the realistic dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$**   
 836 **activities in abyssal because boundary scavenging and sediment resuspensions are**  
 837 **not included in our model. With boundary scavenging and sediment resuspensions**  
 838 **added, dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities in the abyssal should be reduced**  
 839 (Rempfer et al., 2017).

840 A more quantitative model-data comparison is shown in Fig. 5. The linear  
 841 regression coefficient, an indication of model ability to simulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$   
 842 activity (Dutay et al., 2009), is near 1.0 for dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  (1.02 for  
 843  $^{231}\text{Pa}_d$  and 1.14 for  $^{230}\text{Th}_d$ ), suggesting that CTRL can simulate the dissolved  $^{231}\text{Pa}$   
 844 and  $^{230}\text{Th}$  in good agreement with observations. However, the simulation of the  
 845 particulate activity is not as good as the dissolved activity. Particulate activity is  
 846 overall **larger** than observations in the surface ocean and **smaller** than observation

888 in the deep ocean for both ~~particulate~~  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ . The regression coefficient for  
 889 particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  is 0.02 for  $[\text{particulate } ^{231}\text{Pa}]_p$  and 0.05 for  $[\text{particulate } ^{230}\text{Th}]_p$ . The poor  
 890 performance in simulating water column particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities is also  
 891 in previous modeling studies (Dutay et al., 2009; Siddall et al., 2005), because of  
 892 similar modelling scheme are applied. However, the simulated  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  is  
 893 reasonable. The  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  along two GEOTRACES tracks (Fig. 2 and 3) show the  
 894 similar pattern and magnitude as in Rempfer et al., (2017). Decrease of  
 895  $^{231}\text{Pa}_p/^{230}\text{Th}_p$  with depth is well simulated, which is suggested to be caused by the  
 896 lateral transport of  $^{231}\text{Pa}$  from North Atlantic to Southern Ocean by AMOC (Gherardi  
 897 et al., 2009; Lippold et al., 2011, 2012a; Luo et al., 2010; Rempfer et al., 2017).

898 The sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in CTRL is overall consistent with observations,  
 899 (references of observations are listed in Table 3). The North Atlantic shows low  
 900 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio as in observations because  $^{231}\text{Pa}$  is more subject  
 901 to transport southward to the Southern Ocean by active ocean circulation than  $^{230}\text{Th}$   
 902 because of longer residence time. The Southern Ocean maximum in the sediment  
 903  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio is also simulated in CTRL. High opal fluxes in the Southern  
 904 Ocean, which preferentially removes  $^{231}\text{Pa}$  into sediment ( $K_{opal}^{231Pa} > K_{opal}^{230Th}$ ). (Chase  
 905 et al., 2002), leading to increased sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio. In addition,  
 906 upwelling in the Southern Ocean brings up deep water enriched with  $^{231}\text{Pa}$ , which is  
 907 transported from the North Atlantic, to shallower depth and further contribute to  
 908 the scavenging. CTRL can also produce higher sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in  
 909 regions with high particle production (e.g. the Eastern equatorial Pacific, the North  
 910 Pacific and the Indian Ocean) due to the “particle flux effect”. Specifically, in North  
 911 Atlantic, the distribution of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  matches the distribution of  
 912 particle, especially opal, production: sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is higher where opal  
 913 production is high, and vice versa.

#### 914 4.2 Sensitivity on partition coefficient K

916 In this section, we show model sensitivity on partition coefficient by  
 917 increasing and decreasing the partition coefficient, K, by a factor of 5, but keep the

relative ratio for different particles the same (Table 2). Our model shows similar model sensitivity as in Siddall et al., (2005) as discussed below.

Increasing K will decrease water column dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  activities but won't change particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  too much (Fig. 6). Larger K will lead to more  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  attached to particles and further buried into sediment, which increases the sink for the  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  budget. With the sources for  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  staying the same, dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  will be reduced. Increasing K will also reduce the vertical gradient of dissolved  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  as reversible scavenging act as the vertical transport and increase this vertical transport can decrease the vertical gradient. However, change in the particulate  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  is small. As stated in Siddall et al., (2005), if we neglect the transport term and the decay term in Eq. (3) and assume particulate phase activity at the surface as 0, when reach equilibrium, the activity of particulate phase will be as in Eq. (7). The particulate phase activity only depends on the production rate, the particle settling velocity and depth. The particulate phase activity will increase linearly with depth and any departure from this linear relationship with depth is due to ocean transport, which is suggested by observations (Bacon and Anderson, 1982; Roy-Barman et al., 1996). Therefore, changing K will have limited influence on particulate phase activity.

$$A_p^i(z) = \frac{\beta^i}{w_s} \cdot z$$

(7)

Increasing K will also reduce the spatial gradient in sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio and vice versa (Fig. 7). Larger K will decrease the  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  residence time and most isotopes produced in the water column are removed into sediment locally (Table 2). Therefore, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio becomes more homogeneous and approaching the production ration of 0.093 (Fig. 7b). The sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in EXP\_1 and EXP\_2 departures from observations significantly, suggesting the partition coefficient in CTRL is of the right magnitude.

#### 4.3. Sediment $^{231}\text{Pa}/^{230}\text{Th}$ ratio in HOSING

Potential changes in the export of biogenic particles makes using  $^{231}\text{Pa}/^{230}\text{Th}$  ratio to reconstructing AMOC strength under debate. In response to freshwater perturbation in the North Atlantic, both biological productivity and AMOC strength will change and will influence sediment  $^{231}\text{Pa}/^{230}\text{Th}$ . Our model with p-fixed and p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can help detangle these two effects. In this section, we examine the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  (p-fixed and p-coupled) response in the North Atlantic to fresh water perturbation.

In HOSING, after applying freshwater forcing to the North Atlantic, AMOC strength quickly decreases to a minimum of 2 Sv (AMOC\_off) (Fig. 9a). During the AMOC\_off state, compared with CTRL with active AMOC (AMOC\_on), p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  shows an overall increase in the North Atlantic and a decrease in the South Atlantic (Fig. 10b) because of the reduced southward transport of  $^{231}\text{Pa}$  from the North Atlantic by AMOC, consistent with paleo proxy evidence there (e.g. Gherardi et al., 2005, 2009; McManus et al., 2004). The overall increase of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North Atlantic in response to AMOC collapse can be seen more clearly in the time evolution of the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio averaged from  $20^\circ\text{N}$  to  $60^\circ\text{N}$  in the North Atlantic (Fig.9b, green). Quantitatively, the  $^{231}\text{Pa}/^{230}\text{Th}$  increases from 0.074 in AMOC\_on to 0.098 in AMOC\_off in the p-fixed version, approaching the production ration of 0.093. This increase of  $^{231}\text{Pa}/^{230}\text{Th}$  is also in the subtropical North Atlantic from the two sites near Bermuda Rise (Fig. 9e and f), which is of comparable magnitude with the change from LGM to HS1 in reconstructions there (McManus et al., 2004). In addition, the pattern of p-fixed (Fig.10a) sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio during the Atlantic in AMOC\_off state is similar to the opal distribution (Fig.1b) because, without active circulation, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio is more controlled by particle flux effect, which is similar to Pacific in CTRL. It is further noted that our p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in HOSING behaves similarly to that in Siddall et al., (2007).

The overall increase in p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North Atlantic is not homogenous and the magnitude of the change between AMOC\_on and

AMOC\_off varies with location because of the distribution of particle flux, especially opal flux (Fig.9 and 10). The maximum increase in p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio occurs near 40°N western Atlantic, where the opal production in our model is maximum in North Atlantic (Fig. 1b). The sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in this region during AMOC\_on is larger than production ratio of 0.093 because opal maximum provides extra  $^{231}\text{Pa}$  to this region ("particle flux effect"), which overwhelms the active ocean circulation transporting  $^{231}\text{Pa}$  southward outside this region (Fig. 9d, green). During AMOC\_off, without active ocean circulation, the particle flux effect becomes even stronger because less  $^{231}\text{Pa}$  is transported out of the North Atlantic and p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio gets even larger.

Most regions in the Atlantic, p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  show similar response to p-fixed  $^{231}\text{Pa}/^{230}\text{Th}$  in HOSING. The evolution of p-fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in HOSING are highly correlated (Fig. 11a). The change of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio from AMOC\_on to AMOC\_off are similar in both p-fixed and p-coupled version (Fig.11b). The correlation between p-fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio change is 0.72 (1455points) and the linear regression coefficient is 0.71 ( $R^2 = 0.52$ ). High correlation between p-fixed and p-coupled response mainly happens over low productivity region (Fig.1, 10, and 11), where circulation effect on sediment  $^{231}\text{Pa}/^{230}\text{Th}$  is more important than the particle change in HOSING.

However, the responses of p-fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  to the fresh water forcing can differ significantly in high productivity regions because of the change of productivity. With persistent freshwater forcing in the North Atlantic, most regions in the North Atlantic show reduced production of  $\text{CaCO}_3$ , opal and POC (Fig. 8). Productivity in North Atlantic is suggested to be halved during AMOC collapse because of increased stratification, which reduces nutrient supply from deep ocean (Schmittner, 2005). In our model, the productivity in mid-latitude North Atlantic is indeed greatly reduced after the freshwater forcing. For example, opal production from 30°N-50°N in the Atlantic at the end of HOSING is reduced by 50%~90% of its original value in CTRL. However, opal production increases in high latitude North Atlantic at north of 50°N. The pattern of opal production changes

**Deleted:** With the AMOC collapsing, the  $^{231}\text{Pa}/^{230}\text{Th}$  ratio tends to increase over most of the North Atlantic, consistent with paleo proxy evidence there. In HOSING, after applying extra freshwater to the North Atlantic, AMOC strength quickly decreases to a minimum of 2 Sv at around year 300 (AMOC\_off)(Fig. 7a). During the AMOC\_off state, compared with CTRL of active AMOC (AMOC\_on), both abiotic and biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio shows an overall increase in the North Atlantic and a decrease in the South Atlantic (Fig. 8b and d) because of the reduced southward transport of  $^{231}\text{Pa}$  from the North Atlantic by AMOC. In most area of the Atlantic, the evolution of abiotic and biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in HOSING are highly correlated (Fig. 9a). The change of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio from AMOC\_on to AMOC\_off are similar in abiotic and biotic version (Fig.9b). The correlation between abiotic and biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio change is 0.72 (1455points) and the linear regression coefficient is 0.71 ( $R^2 = 0.52$ ). This suggests that abiotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio can capture the major feature of biotic  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in our model and also circulation effect on sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio is more dominant than the biological effect in HOSING. The pattern of abiotic (Fig.8a) sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the Atlantic in AMOC\_off state is similar to the opal distribution (Fig.1b) because, without active circulation, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio is more controlled by particle flux effect, which is similar to the case in the Pacific in CTRL. The overall increase of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North Atlantic in response to AMOC collapse can be seen more clearly in the time evolution of the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio averaged from 20°N to 60°N in the North Atlantic in both the abiotic and biotic  $^{231}\text{Pa}/^{230}\text{Th}$  (Fig.7b). Quantitatively, the  $^{231}\text{Pa}/^{230}\text{Th}$  increases from 0.074 (0.074) in AMOC\_on to 0.098 (0.095) in AMOC\_off in the abiotic (biotic) version (Fig. 7b). Both abiotic and biotic version show average sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North Atlantic near the production ratio of 0.093. This increase of  $^{231}\text{Pa}/^{230}\text{Th}$  in both abiotic and biotic versions is also seen in the subtropical North Atlantic from the two sites near Bermuda Rise (Fig. 7e and f), which is, of comparable magnitude with the change from LGM to HS1 in reconstructions there (McManus et al., 2004). It is further noted that our abiotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in HOSING behaves similarly to that in Siddall et al., (2007). ... [5]

**Deleted:** collapse of AMOC

**Deleted:** show similar behavior over most ocean region of low productivity but

with high opal production region shifts northward in HOSING (Fig. 8 d, e and f). The particle flux change will influence sediment  $^{231}\text{Pa}/^{230}\text{Th}$  as discussed below.

In subpolar region, the opal productivity increases during AMOC off and will result an increase in sediment  $^{231}\text{Pa}/^{230}\text{Th}$ , which is enhance the increase of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  caused by reduced AMOC. Therefore, the increase in p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  between AMOC off and AMOC on is larger than p-fixed sediment  $^{231}\text{Pa}/^{230}\text{Th}$  (Fig.9c).

In the mid-latitude North Atlantic, the opal productivity decreases during AMOC off and will lead to a decrease in sediment  $^{231}\text{Pa}/^{230}\text{Th}$ , which is opposite to the effect of reduced AMOC. Therefore, p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  shows an initial decrease in first 200 years (Fig.9 d, e, and f, red dash) caused by the reduced opal productivity. But this decrease trend is reversed eventually, suggesting the influence of particle flux change is overwhelmed by the effect of reduced AMOC. In the long run, most regions in the subtropical and mid-latitude Atlantic show increased sediment  $^{231}\text{Pa}/^{230}\text{Th}$  in HOSING, indicating the dominant effect of reduced AMOC. But sediment  $^{231}\text{Pa}/^{230}\text{Th}$  at 40°N west Atlantic, where opal productivity is maximum in AMOC on, show a decrease from AMOC on to AMOC off. During AMOC on, the opal productivity maximum at 40°N west Atlantic lead to regional maximum sediment  $^{231}\text{Pa}/^{230}\text{Th}$  because of the particle flux effected, which has been explained previously. During AMOC off, this opal productivity maximum is eliminated and no more extra  $^{231}\text{Pa}$  is supplied by surroundings to this region. The decrease in sediment  $^{231}\text{Pa}/^{230}\text{Th}$  caused by productivity change is larger than the increase caused by the reduced AMOC. Therefore, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  experienced a decrease from AMOC on to AMOC off. Our results suggest that although the circulation effect is more dominant than the particle change in controlling sediment  $^{231}\text{Pa}/^{230}\text{Th}$  on long time scale in most of North Atlantic, particle flux change can be important on short time scale and in high productivity regions. Therefore, we should be cautious when using sediment  $^{231}\text{Pa}/^{230}\text{Th}$  to reconstruct AMOC variations in the past.

Formatted: Superscript

Formatted: Not Superscript/ Subscript

It is suggested that the particulate  $^{231}\text{Pa}/^{230}\text{Th}$  response to the change of AMOC depends on the location and depth. Above 2km and high latitude North Atlantic, particulate  $^{231}\text{Pa}/^{230}\text{Th}$  decreases with the increased AMOC (Rempfer et al., 2017). Our results are consistent with this finding (Fig. 12 a and b). Both p-fixed and p-coupled particulate  $^{231}\text{Pa}/^{230}\text{Th}$  show similar patterns of change between AMOC on and AMOC off: decrease in particulate  $^{231}\text{Pa}/^{230}\text{Th}$  at shallow depth and north of 60°N and increase in particulate  $^{231}\text{Pa}/^{230}\text{Th}$  below 2km and south of 60°N during AMOC off. Therefore, sediment depth should be taken into consideration when interpreting sediment  $^{231}\text{Pa}/^{230}\text{Th}$ . Since the pattern in p-coupled is similar to the pattern in p-fixed, the opposite particulate  $^{231}\text{Pa}/^{230}\text{Th}$  changes in shallow and deep North Atlantic is associated with AMOC. During AMOC on, upper limb of AMOC (about upper 1km) transport water northward, which provides extra  $^{231}\text{Pa}$  to North Atlantic and particulate  $^{231}\text{Pa}/^{230}\text{Th}$  is larger than the production ratio of 0.093. In contrast, the lower limb of AMOC (2km-3km) features southward transport, which transports  $^{231}\text{Pa}$  to the Southern Ocean and particulate  $^{231}\text{Pa}/^{230}\text{Th}$  is smaller than the production ratio of 0.093 (Fig. 12 solid). During AMOC off, ocean transport of  $^{231}\text{Pa}$  is greatly reduced. Therefore, shallow (deep) depth experiences a decrease (increase) in particulate  $^{231}\text{Pa}/^{230}\text{Th}$  and the vertical gradient in the particulate  $^{231}\text{Pa}/^{230}\text{Th}$  is also greatly reduced (Fig. 12 c). Our results support that the depth dependence of particulate  $^{231}\text{Pa}/^{230}\text{Th}$  is mainly caused by lateral transport of  $^{231}\text{Pa}$  by circulation (Gherardi et al., 2009; Lippold et al., 2011, 2012a; Luo et al., 2010; Rempfer et al., 2017).

Overall, our model is able to simulate the correct magnitude of the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio response to the freshwater forcing. Change of circulation has the dominant influence on sediment  $^{231}\text{Pa}/^{230}\text{Th}$  on long time scale over most of regions in the hosing experiment, although the detailed difference between p-fixed and p-coupled sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio response to freshwater forcing in different locations can be complicated.

## 5. Summary

Formatted: Superscript

Formatted: Superscript

Formatted: Superscript

**Deleted:** Productivity in North Atlantic is suggested to be halved during AMOC collapse because of increased stratification, which reduces nutrient supply from deep ocean (Schmittner, 2005). In the CESM, the productivity in mid-latitude North Atlantic is indeed greatly reduced after the freshwater forcing. For example, at year 100 in HOSING, opal production from 30°N-50°N in the Atlantic is reduced by 50%~90% of its original value in CTRL (not shown). Therefore, in the first 100 years in HOSING, most biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio show an initial decrease in the North Atlantic from the subtropics to the mid-latitude (Fig.7 d, e, and f, red dash). In the subpolar region, the productivity is increased in the model, leading to an initial increase of biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio (Fig.7c). Furthermore, the detailed pattern of the difference between AMOC\_off and AMOC\_on in sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio is different.

**Deleted:** For example, the region (near 40°N west Atlantic), which has the maximum increase from AMOC\_on to AMOC\_off in abiotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio discussed above, shows a decrease in biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio (Fig. 7d and Fig.8d) because there is no more opal maximum in this region in AMOC\_off. A detailed discussion of the difference between abiotic and biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in different regions is beyond the scope of this paper.

1198  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  have been implemented in the ocean model of the CESM in  
1199 both the p-coupled and p-fixed forms. Our control experiment under present day  
1200 climate forcing is able to simulate most  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  water column activity and  
1201 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio consistent with observations by using the  
1202 parameters that are suggested by Chase et al., (2002) and used in Siddall et al.  
1203 (2005). Our sensitivity experiments with varying parameters suggest that these  
1204 parameters are of the right magnitude.

1205 Furthermore, our model is able to simulate the overall sediment  $^{231}\text{Pa}/^{230}\text{Th}$   
1206 ratio change in the North Atlantic with a magnitude comparable to the  
1207 reconstruction in response to the collapse of AMOC, although the detailed response  
1208 can be complicated in different regions. Finally, the p-fixed form is able to capture  
1209 many major features of that of the p-coupled form over large ocean areas on long  
1210 time scale, although the two forms can also differ significantly in some regions,  
1211 especially the region with high opal productivity. Therefore, with both p-fixed and  
1212 p-coupled  $^{231}\text{Pa}$  and  $^{230}\text{Th}$ , our model can serve as a useful tool to improve our  
1213 understanding of the processes of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  and also interpretations of  
1214 sediment  $^{231}\text{Pa}/^{230}\text{Th}$  reconstructions for past ocean circulation and climate  
1215 changes.

#### 1216 **Code availability:**

1217 The  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  isotope source code of both p-fixed and p-coupled versions for  
1218 CESM1.3 is included as supplementary material here.

(c) North Atlantic (20°N-60°N) average profile during AMOC\_on (solid) and AMOC\_off (dash) for p-fixed (green) and p-coupled (red) particulate  $^{231}\text{Pa}/^{230}\text{Th}$ .

1742  
1743  
1744  
1745

Two forms of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are implemented in POP2: abiotic and biotic. Abiotic  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  use particle fluxes prescribed as annual mean particle fluxes from the CESM marine ecosystem module under present day climate forcing (Fig.1). Biotic  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  use particle fluxes computed simultaneously from the marine ecosystem module. Abiotic and biotic  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  can be turned on at the case build time and the biotic  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  requires the ecosystem module turned on at the same time.

The implementation of  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  is based on Siddall et al., (2005) (Eq.(3)).  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are produced from the  $\alpha$  decay of  $^{235}\text{U}$  and  $^{234}\text{U}$  uniformly everywhere at constant rate  $\beta^i$  ( $\beta^{\text{Pa}} = 2.33 \cdot 10^{-3} \text{ dpm m}^{-3} \text{ yr}^{-1}$ ,  $\beta^{\text{Th}} = 2.52 \cdot 10^{-2} \text{ dpm m}^{-3} \text{ yr}^{-1}$ ).  $^{231}\text{Pa}$  and  $^{230}\text{Th}$  are subjective to radioactive decay with the decay constant of  $\lambda^i$  ( $\lambda^{\text{Pa}} = 2.13 \cdot 10^{-5} \text{ yr}^{-1}$ ,  $\lambda^{\text{Th}} = 9.22 \cdot 10^{-6} \text{ yr}^{-1}$ ). In addition to ocean transport, which includes advection, convection, and diffusion, another

$$A_t^i = A_d^i + A_p^i \quad (1)$$

$$K_j^i = \frac{A_{j,p}^i}{A_{j,d}^i C_j} \quad (2)$$

where

.

$$A_p^i = A_t^i \cdot \left( 1 - \frac{1}{1 + K_{POC}^i \cdot R_{POC} + K_{CaCO_3}^i \cdot R_{CaCO_3} + K_{opal}^i \cdot R_{opal} + K_{dust}^i \cdot R_{dust}} \right) \quad ($$

With the AMOC collapsing, the  $^{231}\text{Pa}/^{230}\text{Th}$  ratio tends to increase over most of the North Atlantic, consistent with paleo proxy evidence there. In HOSING, after applying extra freshwater to the North Atlantic, AMOC strength quickly decreases to a minimum of 2 Sv at around year 300 (AMOC\_off)(Fig. 7a). During the AMOC\_off state, compared with CTRL of active AMOC (AMOC\_on), both abiotic and biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio shows an

overall increase in the North Atlantic and a decrease in the South Atlantic (Fig. 8b and d) because of the reduced southward transport of  $^{231}\text{Pa}$  from the North Atlantic by AMOC. In most area of the Atlantic, the evolution of abiotic and biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in HOSING are highly correlated (Fig. 9a). The change of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio from AMOC\_on to AMOC\_off are similar in abiotic and biotic version (Fig.9b). The correlation between abiotic and biotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio change is 0.72 (1455 points) and the linear regression coefficient is 0.71 ( $R^2 = 0.52$ ). This suggests that abiotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio can capture the major feature of biotic  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio in our model and also circulation effect on sediment  $^{231}\text{Pa}/^{230}\text{Th}$  activity ratio is more dominant than the biological effect in HOSING. The pattern of abiotic (Fig.8a) sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the Atlantic in AMOC\_off state is similar to the opal distribution (Fig.1b) because, without active circulation, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio is more controlled by particle flux effect, which is similar to the case in the Pacific in CTRL. The overall increase of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North Atlantic in response to AMOC collapse can be seen more clearly in the time evolution of the sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio averaged from  $20^\circ\text{N}$  to  $60^\circ\text{N}$  in the North Atlantic in both the abiotic and biotic  $^{231}\text{Pa}/^{230}\text{Th}$  (Fig.7b). Quantitatively, the  $^{231}\text{Pa}/^{230}\text{Th}$  increases from 0.074 (0.074) in AMOC\_on to 0.098 (0.095) in AMOC\_off in the abiotic (biotic) version (Fig. 7b). Both abiotic and biotic version show average sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in the North Atlantic near the production ratio of 0.093. This increase of  $^{231}\text{Pa}/^{230}\text{Th}$  in both abiotic and biotic versions is also seen in the subtropical North Atlantic from the two sites near Bermuda Rise (Fig. 7e and f), which is, of comparable magnitude with the change from LGM to HS1 in reconstructions there (McManus et al., 2004). It is further noted that our abiotic sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in HOSING behaves similarly to that in Siddall et al., (2007).

In spite of large scale patterns of sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio response, the magnitude of the change between AMOC\_on and AMOC\_off varies with location in both abiotic and biotic version because of the distribution of particle flux (Fig.7 and 8). Take the abiotic version as an example, the maximum increase in sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio occurs near  $40^\circ\text{N}$  western Atlantic, where the opal production in our model is maximum (Fig. 1b). The sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in this region in AMOC\_on is larger than production ratio of 0.093 because particle flux effect due to the opal maximum provides extra  $^{231}\text{Pa}$  to this

region, which overwhelms the active ocean circulation transporting  $^{231}\text{Pa}$  southward outside this region. Therefore, sediment  $^{231}\text{Pa}/^{230}\text{Th}$  ratio in this region gets even larger (e.g. Fig. 7d). In AMOC\_off, without active ocean circulation, the particle flux effect becomes more prominent because less  $^{231}\text{Pa}$  is transported out of the North Atlantic.
