Abstract. An established 1-dimensional model of Shelf Sea Physics and Primary Production (S2P3) has been developed into three different new models: S2P3-NPZ which includes a Nutrient-Phytoplankton-Zooplankton (NPZ) framework, where the grazing rate is no longer fixed, but instead varies over time depending on different functions chosen to represent the predator-prey relationship between zooplankton and phytoplankton; S2P3-Photoacclim which includes a representation of the process of photo-acclimation and flexible stoichiometry in phytoplankton; and S2P3 v8.0 which combines the NPZ framework and the variable stoichiometry of phytoplankton at the same time. These model formulations are compared to buoy and CTD observations, as well as zooplankton biomass and *in situ* phytoplankton physiological parameters obtained in the Central Celtic Sea (CCS). Models were calibrated by comparison to observations of the timing and magnitude of the spring phytoplankton bloom, magnitude of the spring zooplankton bloom, and phytoplankton physiological parameters obtained throughout the water column. A sensitivity study was also performed for each model to understand the effects of individual parameters on model dynamics. Results demonstrate that better agreement with biological observations can be obtained through the addition of representations of photo-acclimation, flexible stoichiometry, and grazing provided these can be adequately constrained.

1 Introduction

Shelf seas are ocean regions where water depth is less than a few hundred metres (~ 200 m) and represent only $\sim 10\%$ by area of the global ocean. However, these systems have a disproportionate importance because of their exceptionally high biological productivity (Holt and Proctor, 2008), being responsible for 15 to 30% of the total oceanic primary production (PP) (Wollast, 1998; Muller-Karger et al., 2005; Davis et al., 2014). Research vessels and remote, autonomous vehicles have been used to study shelf sea regions such as in the SSB programme (<https://www.uk-ssb.org/>), whose aim was to increase the understanding of how physical, chemical and biological processes interact on UK and European shelf seas, collecting observations throughout 2014 and 2015 in different regions of the UK shelf sea, although this data is not synoptic (i.e. it is not sampled at different locations simultaneously). To complement the available data from research vessels, ocean models have been used to study and understand marine biogeochemistry, including a variety of high spatial resolution models to represent the biogeochemistry of shelf seas with high complexity and horizontal spatial resolution (Sharples, 1999, 2008; Edwards et al., 2012; Marsh et al.,

2015).

25

Different models have been developed to study plankton communities, ranging from very simple ones, e.g. the Lotka-Volterra competition model (Volterra, 1926; Lotka, 1932) to more sophisticated ones, adding more degrees of complexity by including representation of the physical processes of advection and diffusion, or more complexity in ecosystem functions through representation of different groups of organisms and/or size structure. For example, coupled models such as the Nucleus for European Modelling of the Ocean (NEMO) and European Regional Seas Ecosystem Model (ERSEM) (Edwards et al., 2012), Regional Oceanic Modelling System (ROMS) (Shchepetkin and McWilliams, 2005), and Finite Volume Community Ocean Model (FVCOM) (Chen et al., 2003). Although complexity can be useful for describing the interacting behaviour of multiple system components, incomplete understanding of the ecology and key processes of the organisms, and the lack of data for validation (Anderson, 2005) can reduce the reliability of predictions. Moreover, simulations of models like NEMO-ERSEM, ROMS, and FVCOM rely on high-performance computing resources and running multiple sensitivity analyses and experiments is difficult. In contrast, simpler models like the Shelf Sea Physics and Primary Production (S2P3) model (Sharples, 1999; Simpson and Sharples, 2012) have been used to study the dynamics of shelf seas and to simulate seasonal stratification with greater computational efficiency by using a 1-D Nutrient-Phytoplankton (NP) model to represent physical and biogeochemical processes in the water column. In temperate shelf seas, away from advective sources such as the shelf break or plumes from rivers, horizontal processes can be neglected in comparison to vertical processes, thus, although S2P3 does not consider advective fluxes it can make a good representation of the dynamics in the water column for temperate shelf seas (Sharples et al., 2006; Sharples, 2008; Marsh et al., 2015).

The S2P3 v7.0 model was introduced and developed in the work of Marsh et al. (2015), where it was outlined that further development of that model would include resolving phytoplankton physiology. In this study, the S2P3 v7.0 model is developed by allowing variations in light intensity to produce phenotypic adjustments in the phytoplankton cells by changing the chlorophyll content of the phytoplankton and, therefore, the cellular absorption cross-section (Macintyre et al., 2002). This phenotypic change in response to variations in the photon flux density is called photo-acclimation (Falkowski and Laroche, 1991; Moore et al., 2006). The main property of photo-acclimation is the reduction of photosynthetic pigment content in response to increased irradiance (Falkowski and Laroche, 1991). Moreover, changes in nutrient availability can further alter cellular chlorophyll and nitrogen quotas (Droop, 1983; Geider et al., 1998), incorporating a combined representation of these two processes (Geider et al., 1998), this new version of S2P3 v7.0 we term S2P3-Photoacclim and relates phytoplankton growth rates to cell quota (Droop, 1983), describing the light-, nutrient-, and temperature-dependencies of phytoplankton growth rate to varying ratios of N : C : Chl (Geider et al., 1998). On the other hand, simpler models using an NPZ or NPZD framework, with the use of nutrients, phytoplankton, zooplankton, and detritus as the main model components (e.g., Steele, 1974; Wroblewski et al., 1988; Anderson, 2005) have shown good agreement with observations in terms of chlorophyll and PP, by simulating the timing and magnitude of the spring phytoplankton bloom in different regions of the ocean. Despite their relative simplicity, NPZ models can be a better option to approach an understanding of the physics and biology of an ecosystem, which lead to

a further development of the S2P3 v7.0 model where the simplest assumption of a fixed proportion of phytoplankton being
60 grazed and remineralised into the DIN pool (grazing rate) is developed into an NPZ framework (S2P3-NPZ model), using a
Holling Type 2 or Ivlev grazing functional response of zooplankton grazing on phytoplankton (Franks, 2002), which shows a
saturating response to increasing food.

A combination of photo-acclimation, flexible stoichiometry, and NPZ framework is then performed to produce a newly devel-
65 oped model called S2P3 v8.0. This paper presents a thorough analysis in terms of sensitivity to biological parameter values in
each new developed model, resulting in differences of the model structure. A comparison between each model demonstrates
how structural differences influence the representation of the spring phytoplankton bloom and annual PP. The aim of this paper
is to provide a better understanding about the predator-prey relationship between zooplankton and phytoplankton, the effects
of photo-acclimation and flexible stoichiometry and thus the importance of these processes for accurate representation of phy-
70 toplankton dynamics in shelf sea modelling.

2 Study region and model setup

This study is focused on the Central Celtic Sea (CCS), a region located in the North-Western (NW) European Shelf, which is
characterised by its tidally dynamic environment and summer stratification (Pingree et al., 1978; Sharples and Holligan, 2006;
75 Hickman et al., 2012). Daily meteorological data, provided by the National Centers for Environmental Predictions (NCEP)
Reanalysis data (<http://www.esrl.noaa.gov/psd>) was used to force the model at the CCS site, located at $49.4^{\circ}N$, $8.6^{\circ}W$. Wind
speed (m s^{-1}), cloud coverage (%), air temperature ($^{\circ}\text{C}$), and relative humidity (%) variables from this dataset were all used
to force each model version.

80 The following description of model setup is applied to each model structure developed in this work. Tidal components consist
of the u-component (semi-major axis) and the v-component (semi-minor axis) for the M_2 , S_2 , and N_2 tidal constituents. This
data was obtained from a fine mesh (12km resolution) covering the UK shelf. Tidal currents are predicted using the Proudman
Oceanographic Laboratory Coastal Ocean Modelling Systems (POLCOMS) 3-D shelf model (Holt et al., 2009; Wakelin et al.,
2009) with an output extracted for the CCS location. Moreover, each model is initialised on 1st January of the first year of
85 simulation with a temperature of 10.10°C at all depths, and water column presumed mixed throughout, including a vertical
resolution of 1m (i.e. 140 vertical levels). Initial values of physical variables are consistent with former studies (Sharples, 1999,
2008; Marsh et al., 2015), whereas initial values of biological variables are based on observations of zooplankton biomass at
the CCS location over winter months of $0.02 \text{ mmol N m}^{-3}$ (Giering et al., 2018); phytoplankton chlorophyll correspond to
a typical winter value for the CCS location of $0.2 \text{ mg Chl m}^{-3}$, and the DIN initial value is 7 mmol N m^{-3} . The initialised
90 variables are only set up at the start of each simulation and do not reset in between years.

3 Model development

The S2P3 v7.0 model can be divided into two different components: a physical part and a biological part. For this research, the model is an improved version of the original described in Sharples et al. (2006) to be compiled and executed in a Unix environment (Marsh et al., 2015), allowing a 1-D representation of physical and biological processes in shelf seas by simulating the seasonal cycle of phytoplankton, water column stratification, and PP at a selected location defined by water depth and tidal current amplitude. The physical part of the model has been greatly described in many other studies (Sharples, 1999; Sharples et al., 2006; Sharples, 2008; Simpson and Sharples, 2012; Marsh et al., 2015) and is not described in this section again. This model uses the turbulence closure scheme based on Canuto et al. (2001). Likewise, the biological part of the S2P3 v7.0 model is described in Marsh et al. (2015) (Figure 1a).

In order to explicitly account for the influence of zooplankton grazing and, hence, predator-prey dynamics, the S2P3 v7.0 model was developed into an NPZ framework. This new version of the model (S2P3-NPZ) includes zooplankton as a state variable, contrary to the S2P3 v7.0 model where grazing was calculated as a fixed seasonal cycle which was represented as a sink term in the phytoplankton tendency equation. Addition of an explicit grazer also allows comparison to zooplankton biomass observations. As within S2P3 v7.0, the biological part of the S2P3-NPZ model calculates phytoplankton biomass in chlorophyll currency ($Phyto_{chl}$; mg Chl m^{-3}). Additionally, phytoplankton are modelled in terms of internal nitrogen (mmol N m^{-3}) represented by $Phyto_N$. Zooplankton biomass and external DIN are modelled in terms of nitrogen (mmol N m^{-3} ; Figure 1b).

The S2P3-Photoacclim model is a new version of the S2P3 v7.0 model, incorporating a more complete representation of phytoplankton physiology (Geider et al., 1998). This model allows phytoplankton to acclimate to changes in light and nutrients, therefore, the ratios of N : C : Chl and characteristics of phytoplankton physiology can vary, allowing direct comparison to physiological data. The biological part of the S2P3-Photoacclim model uses three currencies of phytoplankton biomass: carbon ($Phyto_C$; mg C m^{-3}), nitrogen ($Phyto_N$; mg N m^{-3}), and chlorophyll ($Phyto_{chl}$; mg Chl m^{-3}). The S2P3-Photoacclim model calculates phytoplankton growth as a function of both nitrogen assimilation and carbon fixation (i.e. variable Chl : N and Chl : C ratios). It is assumed that respiration (R) is equal for all cellular components as a function of temperature: $R_C = R_n = R_{chl} = R_{ref}T_{function}$, where R_{ref} (d^{-1}) is a degradation rate constant at a reference temperature (Figure 1c).

The S2P3 v8.0 model describes a combination of zooplankton and physiological acclimation components in order to provide a more realistic representation of the ecosystem dynamics (Figure 1d).

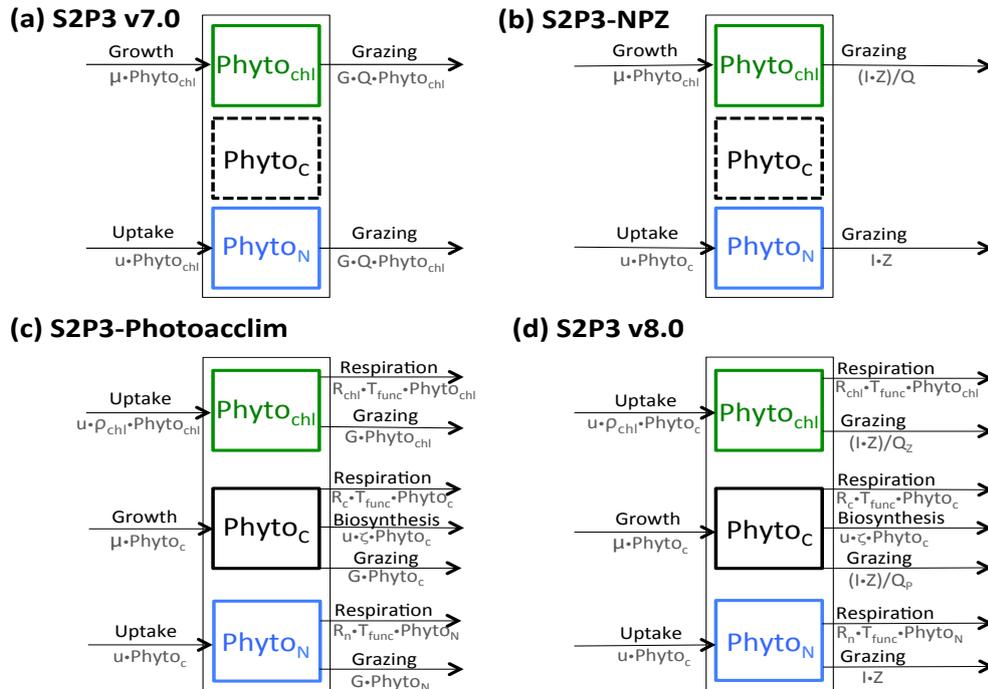

Figure 1. Structure of the phytoplankton growth formulations: (a) S2P3 v7.0 model, with constant $Phyto_N : Phyto_{chl}$ ratio (Q); (b) S2P3-NPZ model, including explicit zooplankton with an associated ingestion rate of phytoplankton (I) based on the Ivlev grazing type; (c) S2P3-Photoacclim model, with varying ratios of $N : C : Chl$, with phytoplankton chlorophyll content regulated by a coefficient of chlorophyll synthesis (ρ_{chl}), which reflects the ratio of energy assimilated to energy absorbed (Geider et al., 1996), and with phytoplankton carbon regulated through a cost associated with biosynthesis ($u\zeta$) (Vries et al., 1974; Geider, 1992; Geider et al., 1998), respiration, and grazing (G); (d) S2P3 v8.0 model, including two different varying quotas for $Phyto_N : Phyto_C$ and $Phyto_N : Phyto_{chl}$.

4 Validation of the models: observations

To calibrate or tune each model, they were adjusted on a trial-and-error basis until disagreement with the *in situ* observations was minimised, allowing investigation of the sensitivity of each model to changes in the parameters listed in Table 1.

4.1 UK SSB programme

Observations were collected throughout the NW European shelf during the spring of 2014 and 2015 as part of the research cruise expeditions DY026, DY018, DY029 and DY033. Samples were collected at the CCS location (Figure 2) during the pre-

130 bloom, peak bloom, and post-bloom conditions of the area. Time-series of surface chlorophyll-*a* concentrations (mg Chl m^{-3}) from long-term mooring deployments including Smartbuoy (Mills et al., 2003) were collected. Moreover, CTD (stainless and titanium) casts were performed in different locations of the NW European shelf from the CCS location to the shelf break, with discrete samples of temperature, DIN, and chlorophyll-*a*. At the CCS location, the CTD samples were collected from pre-dawn to midday with a 1 m vertical resolution over the whole water column (140m depth).

135

4.2 Zooplankton biomass

Zooplankton biomass samples were collected at the CCS location ($49^{\circ}25\text{ N}$, $8^{\circ}35\text{ W}$, $\sim 150\text{ m}$ water depth) during four periods: 5th - 12th August 2014, 10th - 29th November 2014, 3rd - 28th April 2015, and 13th - 31st July 2015 for the cruises DY026, DY018, DY029, and DY033, respectively (Giering et al., 2018). Zooplankton were fractionated into microplankton, small mesozooplankton, and large mesozooplankton by using different mesh sizes. For the S2P3-NPZ and the S2P3 v8.0 models, only mesozooplankton biomass were considered, with a community composition that included: amphipods, appendicularian, chaetogratha, copepods, euphausiacea, polychaeta, and others (e.g. cladocerans, dinoflagellates, echinoderm, eggs, foraminifera, gymnosomata, unidentified larvae, nauplii, ostracods and radiolarian, all of which contributed < 3% in all samples). The complete data set can be obtained from the British Oceanographic Data Centre (BODC), (<http://www.bodc.ac.uk/data>).

145

4.3 Physiological observations

Samples were collected at a number of stations in the Celtic Sea from the cruises JR98 and CD173 (Figure 2). The JR98 cruise was undertaken from 24th July to 14th August of 2003. Stations, from the Irish Sea to the Celtic Sea shelf break, ranged in characteristics from very strong, narrow thermoclines in the southern Celtic Sea (CS1), to the weak, deep surface layer associated with internal wave mixing at the shelf edge (CS2). On the other hand, the CD173 cruise was undertaken from 15th July to 6th August of 2005, from the stratified region of the Celtic Sea shelf (stations D2, CS1, CS3, U2) and shelf break (stations CS2, N1).

155 Photosynthesis versus irradiance (P vs E) experiments were conducted in short-term incubations (2 - 4h) using a photosynthetron (Moore et al., 2006). From these P vs E experiments chlorophyll-*a* normalised PP was derived from ^{14}C uptake to obtain the chlorophyll-*a* specific maximum light-saturated photosynthesis rate $P_{\text{max}}^{\text{Chl}}$ ($\text{mg C (mg Chl - a)}^{-1} \text{ h}^{-1}$) and the maximum light utilisation coefficient, α^{chl} ($\text{mg C (mg Chl-a)}^{-1} \text{ h}^{-1} (\mu\text{E m}^{-2} \text{ s}^{-1})^{-1}$) (Jassby and Platt, 1976; Hickman et al., 2012). Multiple samples were collected in the surface and in deeper layers to obtain different phytoplankton populations throughout the photoperiod. Values of α^{chl} and the light saturation parameter, E_k ($\mu\text{E m}^{-2} \text{ s}^{-1}$) (given by $E_k = P_{\text{max}}^{\text{Chl}}/\alpha^{\text{chl}}$) were spectrally corrected to the *in situ* irradiance at the sample depth according to the phytoplankton light absorption (Moore et al., 2006). For this work, observations from both cruises were used considering only the stations from the seasonally stratified sites

160

(B2, CS1, CS2, CS3, D2, JB1, N1, OB, P1, U2, and ctd16). The maximum light utilisation coefficient (α^{chl}) was constrained for the S2P3-Photoacclim and the S2P3 v8.0 models by finding the mean from all observations: $\alpha^{\text{chl}} = 9.16 \times 10^{-6} \text{ mg C (mg Chl-a)}^{-1} \text{ h}^{-1} (\mu\text{E m}^{-2} \text{ s}^{-1})^{-1}$ (ranges of this parameter accounted from 3.58×10^{-6} to $3.59 \times 10^{-5} \text{ mg C (mg Chl-a)}^{-1} \text{ h}^{-1} (\mu\text{E m}^{-2} \text{ s}^{-1})^{-1}$; std = 4.38×10^{-6}), and therefore, the values of $P_{\text{max}}^{\text{chl}}$ and E_k were used as variables for comparison with equivalent modelled values.

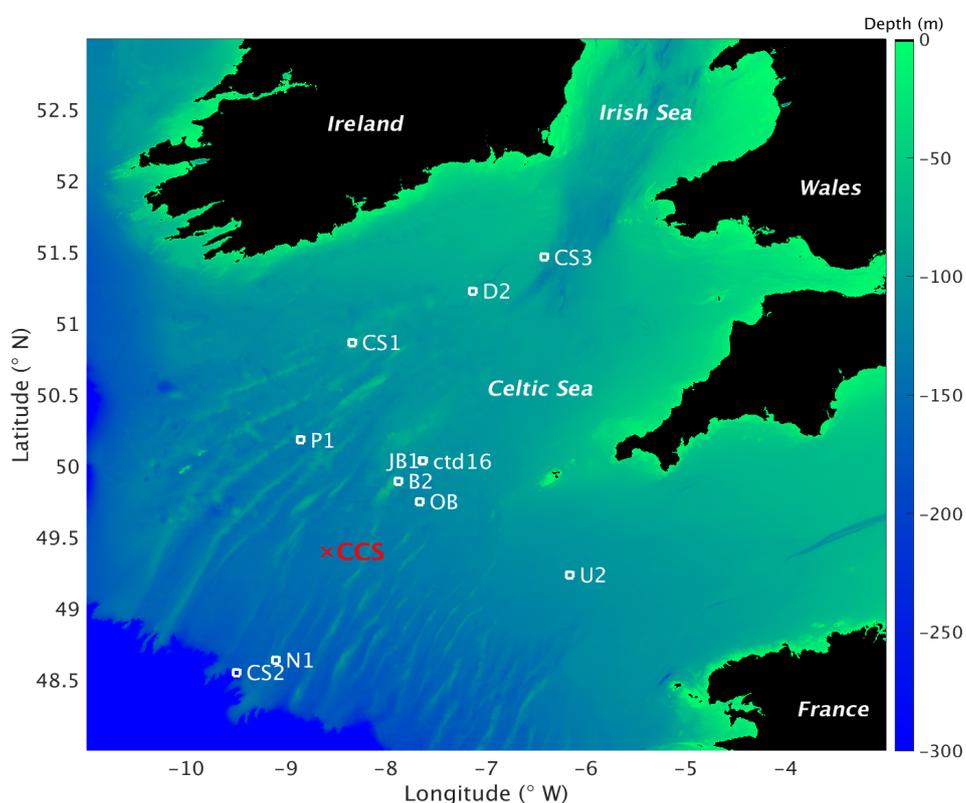

Figure 2. Map for study area and stations for the JR98 and CD173 cruises, including the CCS location (in red colour). Image created with Matlab using the repository data for gridded bathymetry provided by General Bathymetric Chart of the Oceans (GEBCO). Bathymetric data only considered for the shelf sea region (0 to 300m depth) with open ocean depth neglected (deeper than 300m). Continents considered in black colour (over 0m elevation).

Parameters (Units)	Definition	S2P3-NPZ	S2P3-Photoacclim	S2P3 v8.0
γ_1 (dimensionless)	Grazing inefficiency or 'messy feeding' (0.0-1.0), returns a fraction of grazed material back into the DIN pool	0.2		0.1
γ_2 (dimensionless)	Fraction of dead zooplankton (0.0-1.0) that goes into the sediments or higher trophic levels	0.5		0.4
λ (mmol N m ⁻³) ⁻¹	Rate at which saturation is achieved with increasing food levels	0.75		0.2
R_m (d ⁻¹)	Maximum ingestion rate of phytoplankton	2.5		3.5
m (d ⁻¹)	Loss rate of zooplankton due to predation and physiological death	0.05		0.02
P_{max}^C (d ⁻¹)	Maximum value of the carbon-specific rate of photosynthesis		2.0	3.5
Q_m (mmol N (mg C) ⁻¹)	Maximum value of the cellular nutrient quota		0.2	0.45
θ_{max}^N (mg Chl (mmol N) ⁻¹)	Maximum value of the chlorophyll : phytoplankton nitrogen ratio		0.3	0.15
$R_C = R_n = R_{chl}$ (d ⁻¹)	Respiration rates		0	0.02

Table 1. List of parameter values, including units and definitions for the calibrated S2P3-NPZ, S2P3-Photoacclim, and S2P3 v8.0 models.

4.4 Model calibration

170 For this study approximately two years of phytoplankton chlorophyll data were available for the CCS location, while in the
 case of the zooplankton biomass observations, these were collected only during certain days per year allowing only a discrete
 representation of the seasonal cycle of zooplankton. Finally, profiles of physiological data were only collected during sum-
 175 mertime of the years 2003 and 2005. The calibrated version of the S2P3-NPZ model shows differences in the timing of the
 spring phytoplankton bloom for the year 2015 in comparison to observations of surface chlorophyll (Figure 3a), with a later
 bloom from the S2P3-NPZ model, reaching a peak bloom about a month later. Additionally, the magnitude of the spring phy-
 toplankton bloom is also higher in the model in comparison to observations. Phytoplankton are able to escape grazing control
 in April and early May, with the spring zooplankton bloom occurring about a month later (Figure 3b). Similar differences
 can be observed between the calibrated S2P3-Photoacclim model, demonstrating that constraining the timing of the spring
 phytoplankton bloom is a complex process. Tuning model parameters to generate earlier blooms modifies the magnitude of
 180 the spring phytoplankton bloom by increasing it to unrealistic levels. Figure 3 shows that between the three models the best

agreement found in comparison to buoy observations correspond to the S2P3 v8.0 model, although the timing and magnitude of the spring phytoplankton bloom show some remaining small differences, with higher concentrations of surface chlorophyll-*a* during spring ($\sim 10 \text{ mg Chl m}^{-3}$). Moreover, the timing of the spring phytoplankton bloom during the year 2014 matches the observations but a delayed bloom is shown during the year 2015. On the other hand, zooplankton biomass is higher than in the
185 S2P3-NPZ and the predator-prey relationship is well represented, with the spring zooplankton bloom happening approximately a month later than the spring phytoplankton bloom. Remaining mismatches between the calibrated models and observations may be driven by water column processes including advection and diffusion that were not considered in these 1-D models, but affects the real water column where the observations were taken.

190 For the S2P3-NPZ and S2P3-Photoacclim models, CTD observations show that during spring the models have not yet reached the spring phytoplankton bloom whereas observations indicate this is more advanced (Figure 4b), therefore, in the models there are very low chlorophyll-*a* concentrations at the surface and inorganic nutrients have not yet been depleted at this stage. The S2P3 v8.0 model, on the contrary, shows a good agreement in terms of the timing of the spring phytoplankton bloom with the CTD observations. During summer months, the models are able to reproduce the sub-surface mixed layer observed in the CTD
195 profile (Figure 4e), with a similar magnitude but shallower in the case of the S2P3-NPZ and the S2P3 v8.0 model. On the other hand, the physical structure of the model shows a good agreement with the observations during spring (Figure 4a), but there are differences during summer (Figure 4d). The lack of a marked mixed layer depth in all the models is likely related to short term meteorology forcing: during the 24/07/2015, the air temperature was high ($\sim 20 \text{ }^\circ\text{C}$) and wind speed was low ($\sim 5 \text{ m s}^{-1}$). However, the thermocline shows a sharp development in the CTD observations that can not be constrained better in the
200 models by parameterising values of the turbulent closure scheme, light attenuation in the water column, and mixing control parameters (data not shown).

Moreover, the S2P3-Photoacclim and the S2P3 v8.0 models were also evaluated with phytoplankton physiological variability observations (Figure 5), both showing a good agreement with the observations, with plausible values of $P_{\text{max}}^{\text{chl}}$ and E_k found
205 through the water column particularly in terms of the vertical gradients. Calibration of these models against physiological data is relatively novel as such comparisons remain rare. Greater complexity allowed the S2P3 v8.0 model to resolve a more diverse range of biogeochemical dynamics, explicitly accounting for zooplankton biomass and for the dynamics of internal quotas of phytoplanktonic cells, with phytoplankton biomass being in carbon, nitrogen, and chlorophyll currencies, allowing the decoupling of nutrient uptake from carbon fixation (Klausmeier et al., 2004; Flynn, 2008; Bougaran et al., 2010; Bernard,
210 2011; Mairet et al., 2011; Ayata et al., 2013). Including additional parameters in models can add more unconstrained degrees of freedom (Ward et al., 2010), but also allows for more parameter combinations and, therefore, more flexibility to constrain S2P3 v8.0 in order to reproduce observations. The new added parameters and variables in the S2P3 v8.0 model, were carefully chosen to allow the model to be constrained against additional data, specifically zooplankton abundances and photosynthetic physiological measurements, therefore, a higher complexity allowed better representations of the temporal dynamics. Addi-
215 tionally, despite having more sophisticated formulations of the ecosystem, the S2P3 v8.0 model continues to be a 1-D model,

allowing multiple experiments to be run at the same time with relatively low computational cost.

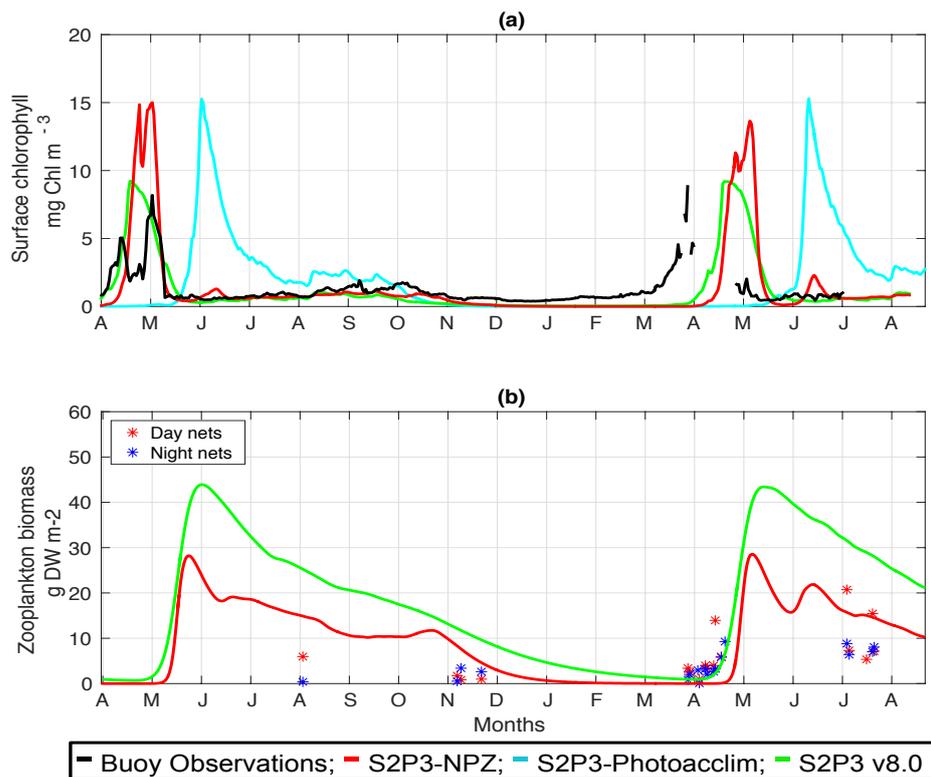

Figure 3. (a) SSB observations of surface chlorophyll-*a* (black line), along with the modelled surface chlorophyll-*a* for the S2P3-NPZ (red line), S2P3-Photoacclim (cyan line), and S2P3 v8.0 (green line) calibrated models. (b) Observations of zooplankton biomass presented as discrete points for day nets (red dots) and night nets (blue dots) taken during the cruises DY026, DY018, DY029, and DY033; modelled zooplankton biomass from the S2P3-NPZ (red line) and S2P3 v8.0 (green line) calibrated models.

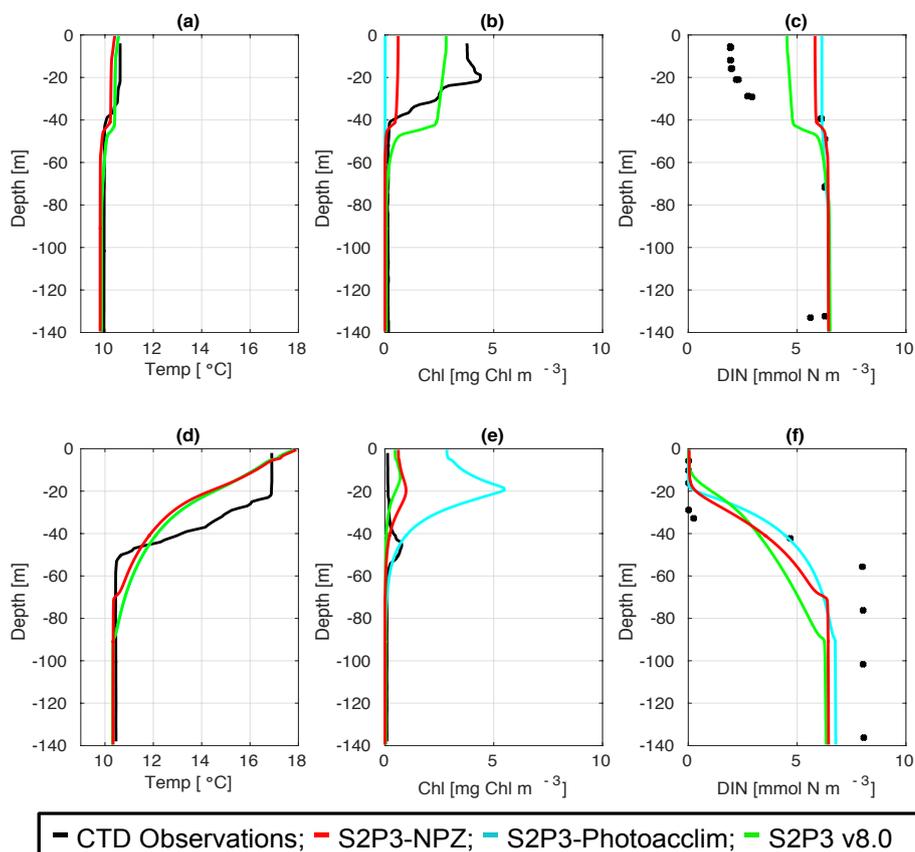

Figure 4. CTD observations from the SSB programme (black lines) including data for: springtime (20/04/2015) (a) temperature, (b) chlorophyll-*a*, and (c) DIN (black dots); for summertime (24/07/2015) (d) temperature, (e) chlorophyll-*a*, and (f) DIN (black dots) along the S2P3-NPZ (red line), S2P3-Photoacclim (cyan line), and S2P3 v8.0 (green line) calibrated models.

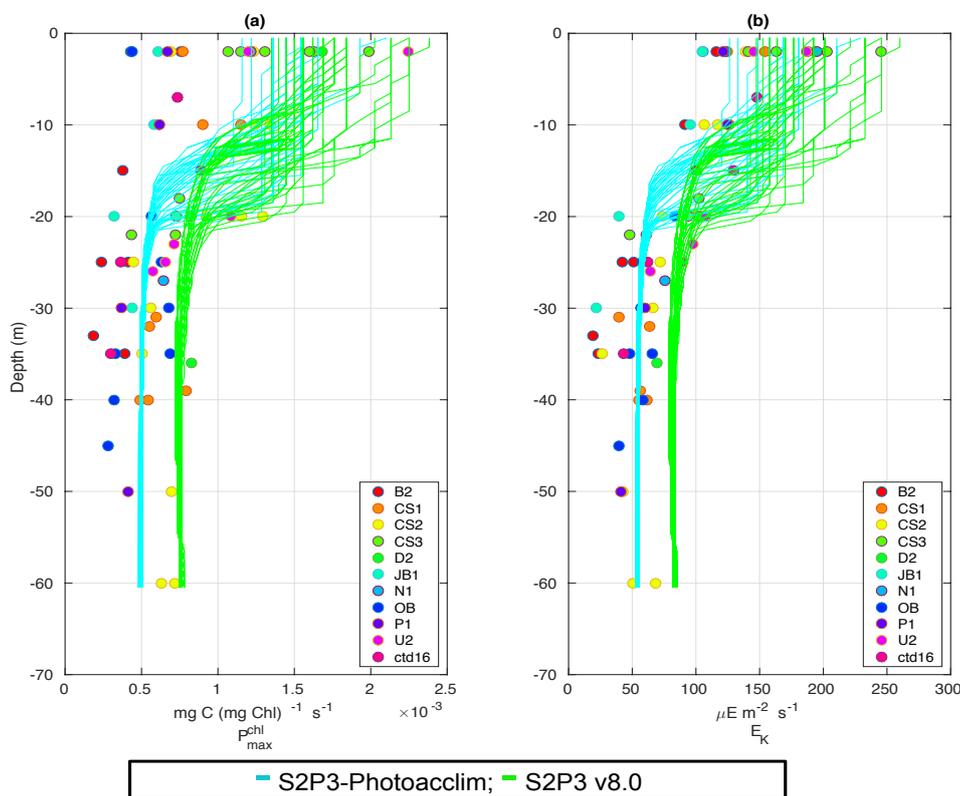

Figure 5. Observations from the cruises CD173 and JR98 for: (a) chlorophyll-a specific maximum light-saturated photosynthesis rate (P_{\max}^{chl}) in different locations of the Celtic Sea and for the calibrated S2P3-Photoacclim model (cyan lines) and the S2P3 v8.0 model (green lines); (b) observations of the light saturation parameter (E_k) for different stations across the Celtic Sea and for the calibrated S2P3-Photoacclim model (cyan lines) and the S2P3 v8.0 model (green lines). The data from both models were plotted for the same days that the observations were collected.

The calibrated version of the S2P3 v8.0 model is displayed in Figures 6 and 7. Figure 6 shows contour plots from daily profiles of the S2P3 v8.0 model for temperature (Figure 6a), phytoplankton chlorophyll-a (Figure 6b), zooplankton biomass (Figure 220 6c), phytoplankton chlorophyll : phytoplankton carbon ratio (Figure 6d), and DIN (Figure 6e) for the years 2014 and 2015 which correspond to the observation period of the SSB programme. Figure 6 allows a more detailed overview of the model dynamics, with yellow colours representing high values of each variable and blue colours representing the lowest values. Water column temperature increases from April of each year, reaching a maximum value at the surface during summer months. At the same time, the spring phytoplankton bloom can be observed during April, reaching $\sim 10 \text{ mg Chl m}^{-3}$. Additionally, the 225 spring zooplankton bloom can be observed approximately a month after the spring phytoplankton bloom is developed, with zooplankton being able to grow during summer months and decreasing until a minimum value during winter. These spring blooms also mark the start of DIN depletion at the surface, a state that lasts until the end of summer. Finally, the phytoplankton chlorophyll : phytoplankton carbon ratio shows the highest values during winter months when irradiance levels are low, with

the Chl : N ratio decreasing until the end of summer due to the lower concentrations of chlorophyll in the cell to avoid internal
230 damage due to high irradiance during this period, highlighting the photo-acclimation of phytoplankton and flexible stoichiometry of the S2P3 v8.0 model.

Figure 7 provides a general overview of the dynamics of the full S2P3 v8.0 model, showing daily time-series from 1965 to 2015
for the calibrated version of this model. Figure 7a shows the start of thermal stratification during early spring with observable
235 inter-annual variability in the extent of stratification. Once the water column is stratified, the spring phytoplankton bloom can
be observed (Figure 7b), followed by the start of the spring zooplankton bloom (Figure 7c). As phytoplankton grows, DIN
concentrations at the surface start to deplete reaching a minimum value during spring and summer months, and increasing
when thermal stratification breaks down during winter months (Figure 7d). Finally, net primary production (NPP) time-series
show seasonal and inter-annual phytoplankton dynamics (Figure 7e).

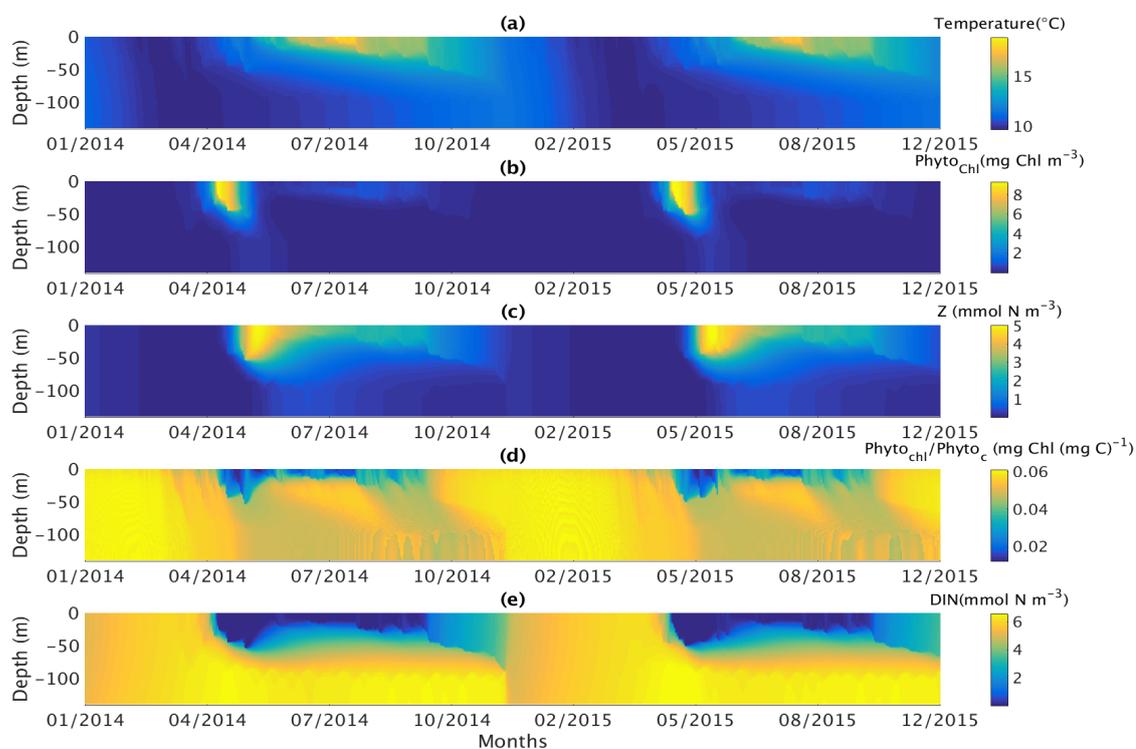

Figure 6. Contoured daily vertical profiles for the start of 2014 to the end of 2015 for the calibrated version of the S2P3 v8.0 model including: (a) temperature (°C), (b) phytoplankton chlorophyll-a (mg Chl m⁻³), (c) zooplankton biomass (mmol N m⁻³), (d) phytoplankton chlorophyll : phytoplankton carbon ratio (mg Chl (mg C)⁻¹), and (e) DIN (mmol N m⁻³).

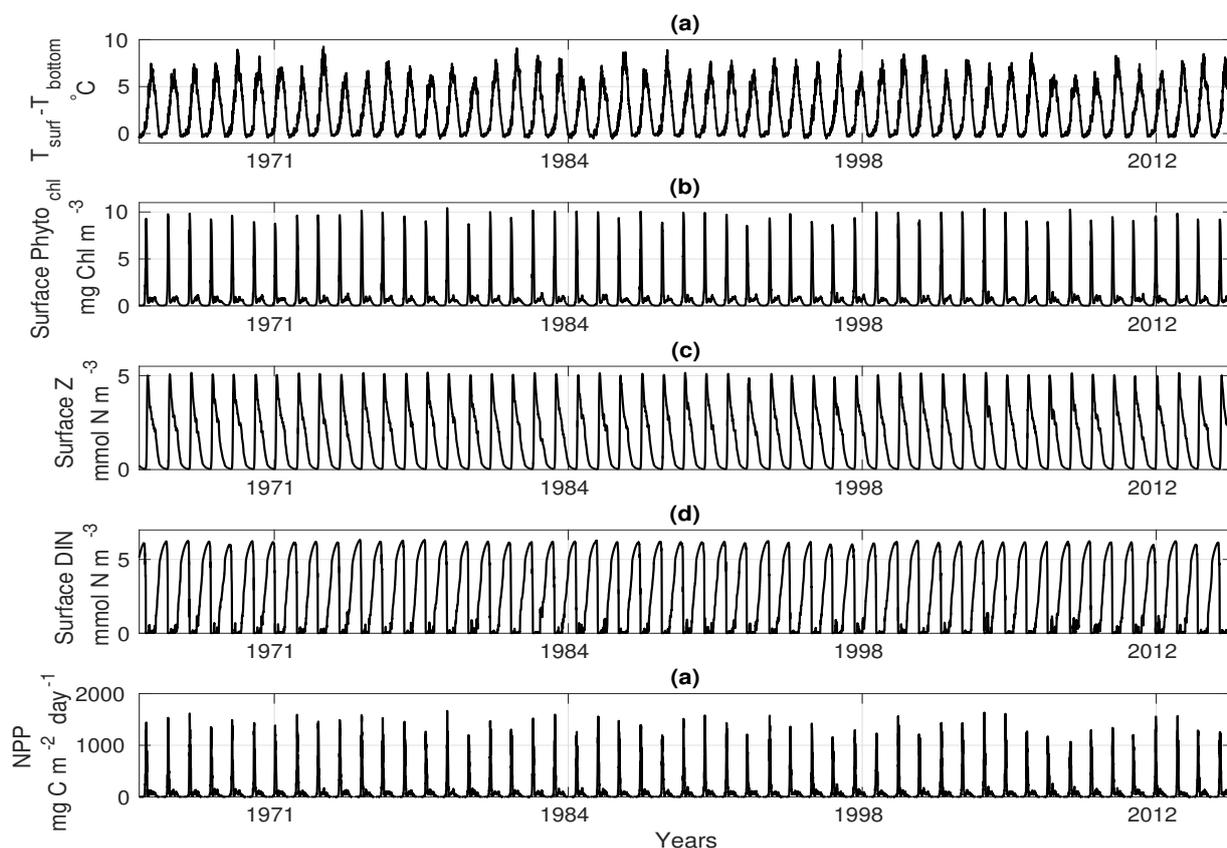

Figure 7. Daily time-series from 1965 to 2015 for the calibrated version of the S2P3 v8.0 model, including: (a) surface temperature minus bottom temperature ($^{\circ}\text{C}$), (b) surface chlorophyll-a (mg Chl m^{-3}), (c) surface zooplankton biomass (mmol N m^{-3}), (d) surface DIN (mmol N m^{-3}), and (e) net primary production (NPP) ($\text{mg C m}^{-2} \text{day}^{-1}$) forced with all meteorological components.

5 Sensitivity studies

An analysis was performed to assess the sensitivity of the model to selected parameter values for the S2P3 v8.0 model. Each parameter listed in Table 1 was varied in turn in order to understand how sensitive the model is to those changes and the effect that they have on the modelled ecosystem dynamics at the CCS location. In each case parameters were varied from the best calibrated value by +50% and -50%. Sensitivity studies are important tools to improve the accuracy of shelf sea models (Chen et al., 2013), but developing these analyses has to be done carefully in order to identify which processes are responsible for the observed model behaviour (Ward et al., 2013). A direct comparison was calculated in terms of the S2P3 v8.0 model attributes

245

considering: the timing and magnitude of the spring phytoplankton bloom, and the total annual zooplankton biomass for the calibrated version of the model and each experiment, providing better insights on the effects that each parameter produces in the behaviour of each model. Table 2 only shows the experiments involving the maximum ingestion rate of phytoplankton (R_m), mortality of zooplankton (m), and the maximum value of the Chl : N ratio (θ_{\max}^N), as they demonstrated to be the most significant parameters in terms of the sensitivity of the model according to the attributes calculated, with the rest of the experiments omitted for this discussion. The S2P3 v8.0 model is strongly influenced by NPZ parameters, with the maximum ingestion rate of phytoplankton (R_m) (Stegert et al., 2007) and zooplankton mortality rate (m) having the largest effect in the magnitude of the spring phytoplankton bloom (Figures A1a, A4a) and in the total annual zooplankton biomass (Figures A1b, A4b). The effects of R_m implies that lower values in the maximum ingestion rate of phytoplankton can produce earlier and larger spring phytoplankton blooms compared to the calibrated S2P3 v8.0 model. On the other hand, a higher value of R_m shows a delayed spring phytoplankton bloom (Figure A2) compared to the CTD observations. Additionally, zooplankton mortality produced differences in the timing of the spring phytoplankton bloom, with delays of 30 days (year 2014) and 35 days (year 2015) when there is less zooplankton mortality, affecting the timing and magnitude of the spring zooplankton bloom, therefore, generating low values of surface chlorophyll-*a* during spring (Figure A5). It is well known that zooplankton are key players in the biogeochemical cycling of carbon and nutrients in marine ecosystems (Beaugrand and Kirby, 2010; Beaugrand et al., 2010), influencing the export of organic matter to the deep ocean (González et al., 2009; Juul-Pedersen et al., 2010). Additionally, grazing responses comprise the dominant losses for phytoplankton in the ocean (Banse, 1994), influencing plankton stocks and primary production (Franks et al., 1986).

Representation of phytoplankton physiology had an important influence on the timing of the spring phytoplankton bloom (Table 2), with θ_{\max}^N affecting the S2P3 v8.0 model the most in terms of this attribute of the model structure, showing less productive and delayed spring blooms when θ_{\max}^N is lower. The spring zooplankton bloom coincides with the timing of the phytoplankton blooms. Ayata et al. (2013) demonstrated that taking into account photoacclimation and variable stoichiometry of phytoplankton growth in marine ecosystem models, produce qualitative and quantitative differences in phytoplankton dynamics. Moreover, these quota formulations in S2P3 v8.0 were compared to the available dataset of physiological observations (Figure A9). It is interesting to note that the sensitivity analysis of NPZ parameters produced differences in the physiological variables P_{\max}^{chl} and E_k , specially at the surface (Figures A3, A6), suggesting that the predator-prey interactions are indirectly influencing phytoplankton physiology, presumably through feedbacks whereby zooplankton mediated nutrient cycling and which subsequently have an effect on phytoplankton physiology. A key point from this study showed that the greater variety of data used in a model, the more constrained the parameter choices seem to get.

Experiments	Years	Timing spring phytoplankton bloom (date)	Magnitude spring phytoplankton bloom (mg Chl m ⁻³)	Total annual zooplankton biomass (g DW m ⁻²)
Calibrated S2P3 v8.0	2014	3 rd April	137.7	6110
	2015	9 th April	172.6	6094
$\theta_{\max}^N \downarrow$	2014	19 th May	103.5	3055
	2015	21 st May	103.1	3514
$\theta_{\max}^N \uparrow$	2014	25 th March	110.2	6733
	2015	27 th March	211.5	6797
$R_m \downarrow$	2014	29 th March	292.5	6840
	2015	3 rd April	359.2	6812
$R_m \uparrow$	2014	14 th April	61.4	5283
	2015	25 th April	159.5	4992
$m \downarrow$	2014	3 rd May	238	8362
	2015	14 th May	203.5	8369
$m \uparrow$	2014	31 st March	104.4	4311
	2015	6 th April	134.5	4368

Table 2. List of the most sensitive experiments run for the S2P3 v8.0 model including the year of observations, timing and magnitude of the spring phytoplankton bloom, and total annual zooplankton biomass values.

6 Comparison of overall model performance

280 The four calibrated models were further tested by running each of the extended period 1965 - 2015, to evaluate the statistics of productivity, partitioned between spring and summer. Table 3 shows that for the S2P3 v7.0 model, on average, 69.2% of the annual phytoplankton production occurs during the spring phytoplankton bloom. On the other hand, for the S2P3-NPZ model, on average, only 37.8% of the annual production occurs during spring months, showing that the predator-prey relationship has a strong influence on the magnitude of the spring phytoplankton bloom every year. Additionally, the S2P3-Photoacclim model

285 shows a very strong spring phytoplankton bloom, corresponding to 97.4% of the total annual NPP. Finally, for the S2P3 v8.0 model, only 67.4% of the annual production corresponds to the spring bloom period. It is clear that, on average, the least productive model overall was S2P3 v8.0, followed by the S2P3-NPZ, S2P3 v7.0, and S2P3-Photoacclim. This shows the impact and complexity that the predator-prey relationship has on the model dynamics, with the addition of explicit zooplankton and their grazing activity as one of the main losses of phytoplankton (Franks et al., 1986). On the other hand, the S2P3 v7.0 model

290 has, on average, more total annual NPP than the S2P3-NPZ model, suggesting that the influence of a constant grazing rate is not as strong in comparison to the one provided by the zooplankton grazing (NPZ framework), because the predator-prey rela-

295 tionship can not be entirely represented in the S2P3 v7.0 model. Additionally, S2P3-Photoacclim had, on average, the highest total annual NPP, demonstrating that the phenotypic responses of phytoplankton to changes in the environment and the addition of variable stoichiometric ratios of N : C : Chl, allows for more efficient phytoplankton, which use the available resources to grow and fix carbon more efficiently.

Model	Characteristic (Units)	Mean	Maximum	Minimum	STD
S2P3 v7.0	Total spring NPP ($g C m^{-2} yr^{-1}$)	39.6	54.7	33.5	5.8
	Total summer NPP ($g C m^{-2} yr^{-1}$)	17.2	22.9	56.9	5.1
	Total annual NPP ($g C m^{-2} yr^{-1}$)	57.1	61.1	53.1	1.8
S2P3-NPZ	Total spring NPP ($g C m^{-2} yr^{-1}$)	21.1	49.3	7.2	9.8
	Total summer NPP ($g C m^{-2} yr^{-1}$)	28.2	39.7	6.8	7.7
	Total annual NPP ($g C m^{-2} yr^{-1}$)	55.7	60.0	52.7	1.5
S2P3-Photoacclim	Total spring NPP ($g C m^{-2} yr^{-1}$)	66.9	76.3	59.9	3.2
	Total summer NPP ($g C m^{-2} yr^{-1}$)	1.1	7.5	0.8	1.1
	Total annual NPP ($g C m^{-2} yr^{-1}$)	68.6	77.6	61.1	3.1
S2P3 v8.0	Total spring NPP ($g C m^{-2} yr^{-1}$)	25.5	39.5	14.5	3.7
	Total summer NPP ($g C m^{-2} yr^{-1}$)	10.3	12.9	6.8	1.1
	Total annual NPP ($g C m^{-2} yr^{-1}$)	37.8	47.8	33.4	2.2

Table 3. Comparison between the S2P3 v7.0, S2P3-NPZ, S2P3-Photoacclim, and S2P3 v8.0 models in terms of the total spring NPP, total summer NPP, and total annual NPP calculated from 1965 to 2015, including the mean, maximum, minimum, and STD values.

7 Conclusions

This study demonstrates that the combination of an NPZ framework, photo-acclimation, and flexible stoichiometry of phytoplankton in one model produces a better representation of the ecosystem based on the comparison to observations. This combined framework offers a novel and innovative improvement to the S2P3 v7.0 model, for application to the CCS location and more broadly within shelf sea systems. The model validation, using both zooplankton biomass and physiological rates of phytoplankton observations are rarely found in the literature, providing a novel contribution to the marine biogeochemistry modelling field of shelf seas. The development of the S2P3 v8.0 model provides a better fit to observations in comparison to the S2P3 v7.0, S2P3-NPZ, and S2P3-Photoacclim models. Improved confidence in the S2P3 v8.0 model thus suggest improved insights in studies about the effects of physical forcing through tides (Sharples, 2008), intra and inter-annual variations in meteorology (Sharples et al., 2006) and other drivers on PP, and phytoplankton dynamics would be possible.

Appropriate parameterisations to represent shelf seas is a subject that should be further supported by fieldwork campaigns and future work should aim to include additional datasets with longer time-series (Friedrichs et al., 2007; Ward et al., 2010). For
310 this study, constraining the seasonal cycle of the phytoplankton physiology is not possible due to the lack of physiological observations during other periods of the year, furthermore, phytoplankton and zooplankton biomass datasets only include the years 2014 and 2015 but longer time-series would help to improve the model calibration. Many model parameters quantities are poorly constrained observationally mainly due to the fact that model state variables are highly integrated pools, which are affected by biotic and abiotic factors in the environment, making them difficult to be determined by *in situ* measurements
315 (Fennel et al., 2001).

The tuning and sensitivity analysis performed in this work allows a better understanding of the ecosystem dynamics represented in the model and how it is influenced by each parameter. By considering the timing and magnitude of the spring phytoplankton bloom, the annual zooplankton biomass, and summer phytoplankton photosynthetic physiology as features to be calculated,
320 a quantitative and clearer comparison between each model could be developed. Finally, the model calibration will never be in perfect agreement with all the observations, particularly in this case, where only one type of phytoplankton and zooplankton were considered. Thus responses must represent some typical or average dynamics and cannot represent any effects of competition between types. Additionally no stages of zooplankton growth were taken into account, which might affect the predator-prey interactions (Wroblewski, 1982; Fennel, 2001). Despite such potential limitations, the S2P3 v8.0 model is able
325 to reasonably represent the integrated behaviour of the mixture of species that inhabit the NW European Shelf Sea.

Code and data availability. S2P3 v8.0

The current version of model is available from <https://doi.org/10.5281/zenodo.3600467> under the Creative Commons Attribution 4.0 International license. The exact version of the model used to produce the results used in this paper is archived on
330 Zenodo (<https://zenodo.org>), as are input data and scripts to run the model and produce the plots for all the simulations presented in this paper.

Unzipped and uncompressed, the directory /s2p3v8.0 contains several sub-directories:

- 335 – /main contains the source code, s2p3_v8.f90, which is compiled “stand-alone”, and executed using accompanying scripts.
- /domain contains, location (latitude and longitude), tidal components, and bathymetry (total depth) for the Central Celtic Sea in the western English Channel (s12_m2_s2_n2_h_tim.dat).
- /met contains 2000 - 2015 meteorological forcing (Falmouth_met_i143_j17_2000 – 2015 ASCII file).

- 340
- /output contains example output data from experiments that show the calibrated version of each model (S2P3v8, S2P3-Photoacclim, and S2P3-NPZ).
 - /plotting contains MATLAB scripts for plotting time-series data from experiments S2P3v8, S2P3-Photoacclim, and S2P3-NPZ. This folder also include all the dataset from observations used to validate each model.

The ancillary files needed for simulations are available on request from the author (e-mail aab1g15@soton.ac.uk).
