1. Shifted Gaussian distributions based on observed patterns

Figure S 1 shows the observed pollen time series over the 2017 season at each of the count sites. We have fitted a normal distribution to these data, minimising the root mean squared error between the fit and the observations. The mean (μ), standard distribution (sd) and fitting parameter (SF) of each individual fit are given in the top left of each panel.

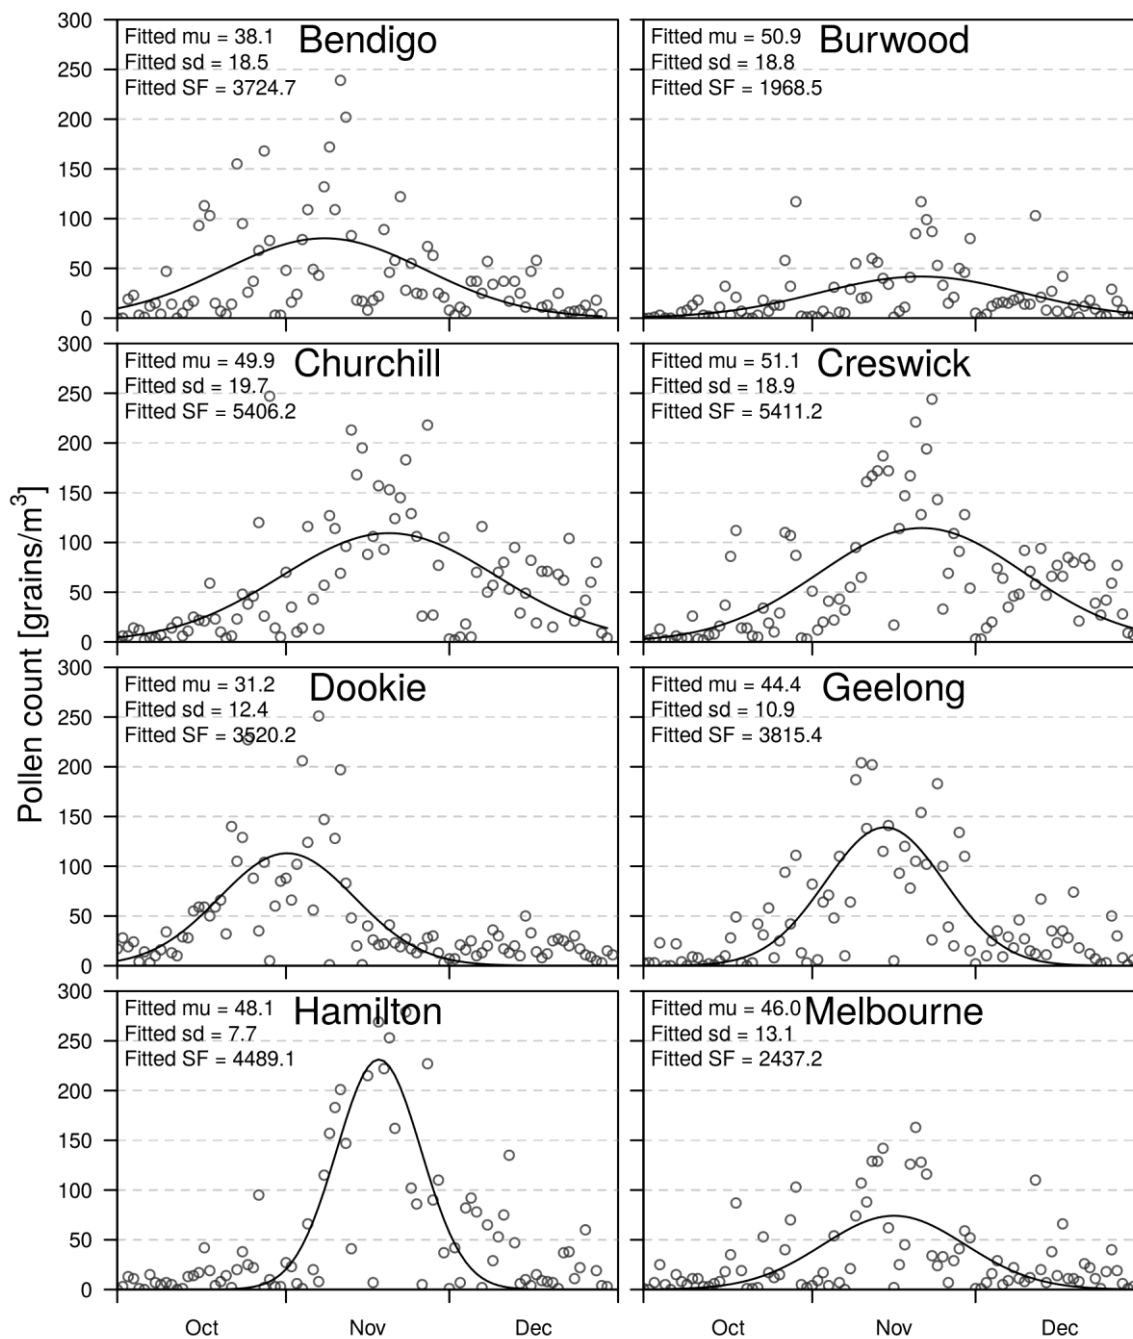

Figure S 1 Time series of observed pollen at each site, which has had a normal distribution fitted to these data.

2. Index of Agreement

The Index of Agreement (IOA) (Willmott et al. 2012) has been calculated using the ModStats package within Openair (Carslaw and Ropkins, 2012). The description of IOA has been taken from the Openair manual (Carslaw, 2015).

IOA spans between -1 and $+1$ with values approaching $+1$ representing better model performance. An IOA of 0.5 , for example, indicates that the sum of the error magnitudes is one half of the sum of the observed-deviation magnitudes. When IOA = 0.0 , it signifies that the sum of the magnitudes of the errors and the sum of the observed-deviation magnitudes are equivalent. When IOA = -0.5 , it indicates that the sum of the error-magnitudes is twice the sum of the perfect model-deviation and observed-deviation magnitudes. Values of IOA near -1.0 can mean that the model estimated deviations about O are poor estimates of the observed deviations; but, they also can mean that there simply is little observed variability — so some caution is needed when the IOA approaches -1 . It is defined as (with $c = 2$):

$$IOA = \begin{cases} 1.0 - \frac{\sum_{i=1}^n |M_i - O_i|}{c \sum_{i=1}^n |O_i - \bar{O}|}, & \text{when} \\ \sum_{i=1}^n |M_i - O_i| \leq c \sum_{i=1}^n |O_i - \bar{O}| \\ \frac{c \sum_{i=1}^n |O_i - \bar{O}|}{\sum_{i=1}^n |M_i - O_i|} - 1.0, & \text{when} \\ \sum_{i=1}^n |M_i - O_i| > c \sum_{i=1}^n |O_i - \bar{O}| \end{cases}$$

3. Gerrity score

For a multi-category forecast we may wish to reward correct forecasts of rare events more than correct forecasts of common events, and penalise forecasts that are badly wrong more than forecasts that are only a little bit wrong. A class of scores called "Gerrity scores" (GS) do just this by multiplying the contingency table by a scoring matrix (which is really a set of weights) and summing to get a score. That is,

		Observed			Scoring matrix		
		L	M	H+			
L		n_{11}	n_{12}	n_{13}	s_{11}	s_{12}	s_{13}

Forecast	M	n_{21}	n_{22}	n_{23}
	H+	n_{31}	n_{32}	n_{33}
	total	n_1	n_2	n_3

 \times

s_{21}	s_{22}	s_{23}
s_{31}	s_{32}	s_{33}

$$GS = \frac{1}{N} \sum_{i=1}^3 \sum_{j=1}^3 n_{ij} s_{ij}$$

GS measures the skill, relative to random chance, of predicting the correct category and ranges from -1 to 1 (perfect). It can be used with multi-category forecasts of any dimension, but is probably most often applied to 3-category forecasts.

The scoring matrix is computed from the climatology (base rate) of the observations, i.e. how often each category occurs, and has nothing to do with the forecasts. You can either use the long-term climatology or the sample climatology. The long-term climatology is better if you have it but it is often the case that you have to estimate it from the sample.

Here are the steps for computing the elements of the scoring matrix:

1. If using the sample climatology, compute the observed relative probability of each category $i=1, 2, 3$ as $p_i = n_i / N$ where n_i is the total number observed in each category and N is the total number of samples.

2. Compute intermediate variables a_i from the relative probabilities,

$$a_1 = (1 - p_1) / p_1 \quad a_2 = (1 - p_1 - p_2) / (p_1 + p_2) \quad a_3 = (1 - p_1 - p_2 - p_3) / (p_1 + p_2 + p_3)$$

3. Compute diagonal elements of the scoring matrix as

$$s_{11} = 0.5 * (a_1 + a_2)$$

$$s_{22} = 0.5 * \left(\frac{1}{a_1} + a_2 \right)$$

$$s_{33} = 0.5 * \left(\frac{1}{a_1} + \frac{1}{a_2} \right)$$

4. Compute off-diagonal elements of the scoring matrix as

$$s_{12} = s_{21} = 0.5 * (a_2 - 1)$$

$$s_{13} = s_{31} = -1$$

$$s_{23} = s_{32} = 0.5 * \left(\frac{1}{a_1} - 1 \right)$$

0.24	- 0.45	- 1.00
- 0.45	1.38	0.83
- 1.00	0.83	6.00

For the Melbourne pollen forecasts, the scoring matrix is $S =$

When multiplied by the 3-category contingency table on the first page we get a Gerrity score for the 1-day forecasts of GS=0.468. It is greater than zero and therefore is a skilful value!

- 5 More information about verification scores is available online at www.cawcr.gov.au/projects/verification.
