It should be noted that to compute GPP from the simulated photosynthesis, it is necessary to add the simulated dark respiration: $\text{GPP} = \text{Ac} + \text{Rdparam} \times \text{Vcmax25} \times \text{LAI}$. In other words, for actual GPP simulation leaf respiration should be disabled, setting Rdparam to 0. The difference with some other canopy-scale models is that SCOPE applies the FvCB model at leaf level (disaggregated), whereas many other models apply this model at aggregated (big leaf or sun-shade model) scales. Our hypothesis is that this results in higher required Vcmax25 values on SCOPE compared to other models. This is an important topic, which requires a detailed investigation.
