10 **Abstract**

11 We describe the development of a non-hydrostatic version of the regional climate model
12 RegCM4, called RegCM4-NH, for use at convection-permitting resolutions. The non-
13 hydrostatic dynamical core of the Mesoscale Model MM5 is introduced in the RegCM4,
14 with some modifications to increase stability and applicability of the model to long-term
15 climate simulations. Newly available explicit microphysics schemes are also described,
16 and three case studies of intense convection events are carried out in order to illustrate
17 the performance of the model. They are all run at convection-permitting grid spacing of 3
18 km over domains in northern California, Texas and the Lake Victoria region, without the
19 use of parameterized cumulus convection. A substantial improvement is found in [several](#)
20 [aspects of](#) the simulations compared to corresponding coarser resolution (12 km) runs
21 completed with the hydrostatic version of the model employing parameterized convection.
22 RegCM4-NH is currently being used in different projects for regional climate simulations
23 at convection-permitting resolutions, and is intended to be a resource for users of the
24 RegCM modeling system.

28 **Introduction**

29 Since the pioneering work of Dickinson et al. (1989) and Giorgi and Bates (1989),
30 [documenting the first regional climate modeling system \(RegCM, version 1\) in literature,](#)
31 the dynamical downscaling technique based on limited area Regional Climate Models
32 (RCMs) has been widely used worldwide, and a number of RCM systems have been

Deleted:

34 developed (Giorgi 2019). RegCM1 (Dickinson et al., 1989, Giorgi and Bates, 1989), was
 35 originally developed at the National Center for Atmospheric Research (NCAR), based on
 36 the Mesoscale Model version 4 (MM4) (Anthes et al, 1987). Then, further model versions
 37 followed: RegCM2 (Giorgi et al. 1993a,b), RegCM2.5, (Giorgi and Mearns 1999),
 38 RegCM3 (Pal et al. 2007), and lastly RegCM4 (Giorgi et al 2012). Except for the transition
 39 from RegCM1 to RegCM2, in which the model dynamical core was updated from that of
 40 the MM4 to that of the MM5 (Grell et al. 1995), these model evolutions were mostly based
 41 on additions of new and more advanced physics packages. RegCM4 is today used by a
 42 large community for numerous projects and applications, from process studies to paleo
 43 and future climate projections, including participation in the Coordinated Regional
 44 Downscaling EXperiment (CORDEX, Giorgi et al. 2009; Gutowski et al. 2016). The model
 45 can also be coupled with ocean, land and chemistry/aerosol modules in a fully interactive
 46 way (Sitz et al. 2017).

47 The dynamical core of the standard version of RegCM4 is hydrostatic, with sigma-p
 48 vertical coordinates. As a result, the model can be effectively run for grid spacings of ~10
 49 km or larger, for which the hydrostatic assumption is valid. However, the RCM community
 50 is rapidly moving to higher resolutions of a few km, i.e. "convection-permitting" (Prein et
 51 al. 2015; Coppola et al. 2020) and therefore the dynamical core of RegCM4 has been
 52 upgraded to include a non-hydrostatic dynamics representation usable for very high
 53 resolution applications. This upgrade, which we name RegCM4-NH, is essentially based
 54 on the implementation of the MM5 non-hydrostatic dynamical core within the RegCM4
 55 framework, which has an entirely different set of model physics compared to MM5.

56

57 RegCM4-NH is already being used in some international projects focusing on climate
 58 simulations at convection-permitting km-scales, namely the European Climate Prediction
 59 System (EUCP, Hewitt and Lowe 2018) and the CORDEX Flagship Pilot Study dedicated
 60 to convection (CORDEX-FPSCONV, Coppola et al. 2020), and it is starting to be used
 61 more broadly by the RegCM modeling community.

62 For example, the recent papers by Ban et al. (2021) and Pichelli et al. (2021) document
 63 results of the first multi-model experiment of 10-year simulations at the convection-
 64 permitting scales over the so-called greater Alpine region. Two different simulations with
 65 RegCM4-NH for present day conditions, have contributed to the evaluation analysis of
 66 Ban et al. (2021). They were carried out at the International Centre for Theoretical Physics
 67 (ICTP) and the Croatian Meteorological and Hydrological Service (DHMZ) using two
 68 different physics configurations. The results show that RegCM4-NH largely improves the
 69 precipitation simulation as compared to available fine scale observations when going from
 70 coarse to high resolution, in particular for higher order statistics, such as precipitation
 71 extremes and hourly intensity, Pichelli et al. (2021) then analyse multi-model ensemble
 72 simulations driven by selected CMIP5 GCM projections for the decades 1996–2005 and
 73 2090–2099 under the RCP8.5 scenario. ICTP contributed to the experiment with

185
186 In this paper we describe the structure of RegCM4-NH and provide some illustrative
187 examples of its performance, so that model users can have a basic reference providing
188 them with background information on the model. In the next section we first describe the
189 new model dynamical core, while the illustrative applications are presented in section 4.
190 Section 5 finally provides some discussion of future developments planned for the RegCM
191 system.

193 Model description

194 In the development of RegCM4-NH, the RegCM4 as described by Giorgi et al. (2012) was
195 modified to include the non-hydrostatic dynamical core (*idynamic* = 2 namelist option as
196 described in RegCM-4.7.1/Doc/README.namelist of the source code) of the mesoscale
197 model MM5 (Grell et al. 1995). This dynamical core was selected because RegCM4
198 already has the same grid and variable structure as MM5 in its hydrostatic core, which
199 substantially facilitated its implementation (Elguindi et al. 2017).

200
201 The model equations with complete description of the Coriolis force and a top radiative
202 boundary condition, along with the finite differencing scheme, are given in Grell et al.
203 (1995). Pressure, p , temperature, T , and density, ρ , are first decomposed into a
204 prescribed reference vertical profile plus a time varying perturbation. The prognostic
205 equations are then calculated using the pressure perturbation values. Compared to the
206 original MM5 dynamical core, the following modifications were implemented in order to
207 achieve increased stability for long term climate simulations (Elguindi et al. 2017
208 document any modifications which follow the choice of the non-hydrostatic dynamical
209 core through the namelist parameter *idynamic* = 2; further available user-dependant
210 options, and the corresponding section in the namelist, are explicitly indicated):

211
212 i) The reference state temperature profile is computed using a latitude dependent
213 climatological temperature distribution and thus is a function of the specific domain
214 coordinates (*base_state_pressure*, *logp_lrate* parameters in *&referenceatm*) (Elguindi et
215 al. 2017). These two parameters were hard-coded in the original MM5 while for the
216 RegCM are user configurable;

Deleted: surface

Commented [1]: added the configurability comment here-

234 ii) The lateral time dependent boundary conditions (*iboudy* in *&physicsparam*) for each
 235 prognostic variable use the same exponential relaxation technique (*iboudy* = 5) described
 236 in Giorgi et al. (1993). The linear MM5 relaxation scheme is [also](#) kept as an option (*iboudy*
 237 = 1);

Deleted: only

238
 239 iii) The advection term in the model equations, which in the MM5 code is implemented
 240 using a centered finite difference approach, was changed to include a greater upstream
 241 weight factor as a function of the local Courant number (Elguindi et al. 2017). The
 242 maximum value of the weight factor is user configurable (*uoffc* in *&dynparam*). As detailed
 243 in the MM5 model description (Grell et al, 1995), the horizontal advection term for a scalar
 244 variable X contributes to the total tendency as:

$$\Delta_{adv}(p^*X)_G = -m^2|_G \left[\frac{(p^*X|_{b\frac{u}{m}}|_b - p^*X|_{a\frac{u}{m}}|_a)}{dx} + \frac{(p^*X|_{d\frac{v}{m}}|_d - p^*X|_{c\frac{v}{m}}|_c)}{dy} \right]$$

246
 247 where the *m* is the projection mapping factor and, with respect to Figure 1, assuming that
 248 the computation is to be performed for the gold cross point *G*, the averages are performed
 249 in the points *a, b, c, d*. For the *u/m* and *v/m* terms, the average value is computed using
 250 respectively the values in points *AC, BD, CD, AB*.

Commented [2]: Added the equation description-

251
 252 In RegCM4 for the term *p^*X*, the model computes a weighted average value of the field
 253 using the value in gold+cyan and gold+green cross points with weights increasing the
 254 relative contribution of the upstream point up as a function of the local courant number:

$$\begin{aligned} 255 \quad p^*X|_a &= 0.5((1 - f_1)p^*X|_G + (1 + f_1)p^*X|_{c_1}) \\ 256 \quad p^*X|_b &= 0.5((1 - f_1)p^*X|_{c_2} + (1 + f_1)p^*X|_G) \\ 257 \quad p^*X|_c &= 0.5((1 - f_2)p^*X|_G + (1 + f_2)p^*X|_{g_1}) \\ 258 \quad p^*X|_d &= 0.5((1 - f_2)p^*X|_{g_2} + (1 + f_2)p^*X|_G) \end{aligned}$$

259 where *f₁*, *f₂* are defined as the local Courant number for the 1D advection equations
 260 multiplied for a control factor:

$$\begin{aligned} 261 \quad f_1 &= \mu_{fc}dt \frac{(u|_a + u|_b)}{2dx} \\ 262 \quad f_2 &= \mu_{fc}dt \frac{(v|_c + v|_d)}{2dy} ; \end{aligned}$$

Commented [3]: Added equation description

265

 295
 296

iv) The water species (cloud, ice, rain, snow) term uses the same advection scheme as the other variables (Elguindi et al. 2017) and not a complete upstream scheme as in the MM5 code (Grell et al. 1995);

Deleted: moisture

v) A local flux limiter reduces the advection terms in order to remove unrealistic strong gradients and its limits are user configurable (in the &dynparam section the maximum gradient fraction for advection; temperature, t_extrema, specific humidity, q_rel_extrema, liquid cloud content, c_rel_extrema and for tracers, t_rel_extrema). This was hardcoded in the MM5 code and the limits were not user configurable;

Deleted: to stop for

vi) The diffusion stencil of the Laplace equation uses a nine point approach as in LeVeque (2006) and a topography dependent environmental diffusion coefficient is added to reduce spurious diffusion along pressure coordinate slopes (Elguindi et al. 2017) as in the hydrostatic version of the code (Giorgi et al. 1993b). The change in stencil does not affect the overall fourth order precision of the model, but reduces the computational stencil size, thus reducing the communication overhead;

Deleted: used

vii) The top boundary radiative condition (ifupr = 1 in &nonhydroparam) adopted in the semi-implicit vertical differencing scheme to reduce the reflection of energy waves uses coefficients on a 13x13 matrix which are re-computed every simulation day and not kept constant throughout the whole simulation as in the MM5 code. This allows the model to be run for longer simulation times while not being strongly tied to the initial atmospheric conditions;

300 viii) The dynamical control parameter β in the semi-implicit vertical differencing scheme
 301 (*nhbet* in *&nonhydroparam*) used for acoustic wave damping (Elguindi et al. 2017) is user
 302 configurable (Klemp and Dudhia, 2008), while it is hard-coded in the MM5;

Deleted: is
 Deleted: and
 Deleted: code

304 ix) A Rayleigh damping (*ifrayd* = 1 in *&nonhydroparam*) of the status variables towards
 305 the input GCM boundary conditions can be activated in the top layers (*rayndamp*
 306 configuring the number of top levels to apply) with a configurable relaxation time
 307 (*rayalpha0*, Klemp and Lilly, 1978, Durran and Klemp, 1983. This is consistent to what is
 308 implemented in the WRF model);

309 x) The water species time filtering uses the Williams (2009) modified filter with $\alpha = 0.53$
 310 instead of the RA filter used by all the other variables. The v factor in the RA filter is user
 311 configurable (*gnu1* and *gnu2* in *&dynparam*). This reduces the damping introduced by the
 312 Robert-Asselin filter and the computational diffusion introduced by the horizontal
 313 advection scheme.

314 With these modifications, the model basic equations, under leap-frog integration scheme,
 315 are, (Elguindi et al. 2017) :

Deleted: the (same as in the MM5) and namely

$$m^2 p^* \gamma p \left[\frac{\partial u / m}{\partial x} - \frac{\sigma}{m p^*} \frac{\partial p^*}{\partial x} \frac{\partial u}{\partial \sigma} + \frac{\partial v / m}{\partial y} - \frac{\sigma}{m p^*} \frac{\partial p^*}{\partial y} \frac{\partial v}{\partial \sigma} \right] + \rho_0 g \gamma p \frac{\partial w}{\partial \sigma} + p^* \rho_0 g \quad (4)$$

332

$$\frac{\partial p^* T}{\partial t} = -m^2 \left[\frac{\partial p^* u T/m}{\partial x} + \frac{\partial p^* v T/m}{\partial y} \right] - \frac{\partial p^* T \dot{\sigma}}{\partial \sigma} + T DIV + \frac{1}{\rho c_p} \left[p^* \frac{Dp'}{Dt} - \rho_0 g p^* w - D_{p'} \right] + p^* \frac{\dot{Q}}{c_p} + D_T \quad (5)$$

333

334

335

Where:

336

$$DIV = m^2 \left[\frac{\partial p^* u/m}{\partial x} + \frac{\partial p^* v/m}{\partial y} \right] + \frac{\partial p^* \dot{\sigma}}{\partial \sigma}$$

337

$$\dot{\sigma} = -\frac{\rho_0 g}{p^*} w - \frac{m \sigma}{p^*} \frac{\partial p^*}{\partial x} u - \frac{m \sigma}{p^*} \frac{\partial p^*}{\partial y} v$$

338

$$\tan \theta = -\cos \phi \frac{\partial \lambda / \partial y}{\partial \phi / \partial x}$$

339

$$p(x, y, z, t) = p_0(z) + p'(x, y, z, t)$$

340

$$T(x, y, z, t) = T_0(z) + T'(x, y, z, t)$$

341

$$\rho(x, y, z, t) = \rho_0(z) + \rho'(x, y, z, t)$$

342

with the vertical sigma coordinate, defined as:

343

$$\sigma = \frac{(p_0 - p_t)}{(p_s - p_t)}$$

344

345

where p_s is the surface pressure and p_0 is the reference pressure profile. The total pressure

346

at each grid point is thus given as:

347

348

349

$$p(x, y, z, t) = p^* \sigma(k) + p_t + p'(x, y, z, t)$$

350

351

With p_t being the top model pressure assuming a fixed rigid lid.

354 The model physics schemes for boundary layer, radiative transfer, land and ocean
 355 surface processes, cloud and precipitation processes are extensively described in Giorgi
 356 et al. (2012) and [summarized in Table 1](#). For each physics component a number of
 357 parameterization options are available ([Table 1](#)), and can be selected using a switch
 358 selected by the user. As mentioned, the use of non-hydrostatic dynamics is especially
 359 important when going to convection-permitting resolutions of a few km (Prein et al. 2015).
 360 At these resolutions the scale separation assumption underlying the use of cumulus
 361 convection schemes is not valid any more, and explicit cloud microphysics
 362 representations are necessary. The RegCM4 currently includes two newly implemented
 363 microphysics schemes, the Nogherotto-Tompkins (Nogherotto et al. 2016) and the WSM5
 364 scheme from the Weather Research Forecast (WRF, Skamarok et al. 2008) model, which
 365 are briefly described in the next sections for information to model users.

376 *Nogherotto-Tompkins Scheme:*

377 A new parameterization for explicit cloud microphysics and precipitation built upon the
378 European Centre for Medium Weather Forecast's Integrated Forecast System (IFS)
379 module (Tiedtke, 1993, Tompkins, 2007), was introduced in RegCM4 (*ipptls* = 2 in
380 *µparam*) by Nogherotto et al. (2016). In the present configuration, the scheme
381 implicitly solves 5 prognostic equations for water vapor, *qv*, cloud liquid water, *ql*, rain, *qr*,
382 cloud ice, *qi*, and snow, *qs*, but it is also easily extendable to a larger number of variables.
383 Water vapor, cloud liquid water, rain, cloud ice and snow are all expressed in terms of the
384 grid-mean mixing ratio.

385 Cloud liquid and ice water content are independent, allowing the existence of supercooled
386 liquid water and mixed-phase clouds. Rain and snow precipitate with a fixed terminal fall
387 speed and can then be advected by the three dimensional winds. A check for the
388 conservation of enthalpy and of total moisture is ensured at the end of each timestep. The
389 governing equation for each variable is:
390

$$\frac{\partial q_x}{\partial t} = S_x + \frac{1}{\rho} \frac{\partial}{\partial z} (\rho V_x q_x)$$

391
392

393 The local variation of the mixing ratio *qx* of the variable *x* is given by the sum of *Sx*,
394 containing the net sources and sinks of *qx* through microphysical processes (i.e.
395 condensation, evaporation, auto-conversion, melting, etc.), and the sedimentation term,
396 which is a function of the fall speed *Vx*. An upstream approach is employed to solve the
397 equations. The sources and sinks contributors are divided in two groups according to the
398 duration of the process they describe: processes that are considered to be fast relative to
399 the model time step are treated implicitly while slow processes are treated explicitly. The
400 processes taken into account (shown in Figure 2) are the microphysical pathways across
401 the 5 water variables: condensation, autoconversion, evaporation, cloud water collection
402 (accretion), and autoconversion for warm clouds, and freezing, melting, deposition,
403 sublimation for cold clouds.

413 **Figure 2: Depiction of the new scheme, showing the five prognostic variables and**
 414 **how they are related to each other through microphysical processes**

Deleted: 1

415 For each microphysical pathway, phase changes are associated with the release or
 416 absorption of latent heat, which then impacts the temperature budget. The impact is
 417 calculated using the conservation of liquid water temperature T_L defined as:
 418

419
$$T_L = T - \frac{L_v}{C_p}(q_l + q_r) - \frac{L_s}{C_p}(q_i + q_s).$$

420 Given that $dT_L = 0$, the rate of change of the temperature is given by the following
 421 equation:

422
$$\frac{\partial T}{\partial t} = \sum_{x=1}^m \frac{L(x)}{C_p} \left(\frac{dq_x}{dt} - D_{q_x} - \frac{1}{\rho} \frac{\partial}{\partial z} (\rho V_x q_x) \right)$$

423
 424

425 where $L(x)$ is the latent heat of fusion or evaporation, depending on the process
 426 considered, D_{q_x} is the convective detrainment and the third term in brackets is the
 427 sedimentation term.

428 At the end of each time step a check is carried out of the conservation of total water and
 429 moist static energy: $h = C_p T + gz + Lq_x.$

430 The scheme is tunable through parameters in the *µparam* section of the namelist
 431 (RegCM-4.7.1/Doc/README.namelist; Elguindi et al. 2017).

433 *WSM5 Scheme:*

434 RegCM4-NH also employs the Single-Moment 5-class microphysics scheme of the WRF
435 model (Skamarock et al., 2008). This scheme (*ipptls* = 3 in *µparam*) follows Hong
436 et al. (2004) and, similarly to Nogherotto et al. (2016), includes vapor, rain, snow, cloud
437 ice, and cloud water hydrometeors. The scheme separately treats ice and water
438 saturation processes, assuming water hydrometeors for temperatures above freezing,
439 and cloud ice and snow below the freezing level (Dudhia, 1989, Hong et al., 1998). It
440 accounts for supercooled water and a gradual melting of snow below the melting layer
441 (Hong et al., 2004, and Hong and Lim, 2006). Therefore, the WSM5 and Nogherotto-
442 Tompkins schemes have similar structures (Figure 2), but also important differences.

Deleted: 1

443 Differently from the Nogherotto-Tompkins scheme, the WSM5 (as well as the other WSM
444 schemes in WRF) prescribes an inverse exponential continuous distribution of particle
445 size (ex. Marshall and Palmer (1948) for rain, Gunn and Marshall (1958) for snow). It also
446 includes the size distribution of ice particles and, as a major novelty, the definition of the
447 number of ice crystals based on ice mass content rather than temperature. Both the
448 Nogherotto-Tompkins and WSM5 schemes include autoconversion, i.e. sub-time step
449 processes of conversion of cloud water to rain and cloud ice to snow. For rain, Hong et
450 al. (2004) use a Kessler (1969) type algorithm in WSM5, but with a stronger physical basis
451 following Tripoli and Cotton (1980). The Nogherotto-Tompkins scheme also includes the
452 original Kessler (1969) formula as an option, but it makes available other three
453 exponential approaches following Sundqvist et al. (1989), Beheng (1994), and
454 Khairoutdinov and Kogan (2000). For ice autoconversion the Nogherotto-Tompkins
455 scheme uses an exponential approach (Sundqvist, 1989) with a specific coefficient for ice
456 particles (following Lin et al., 1983) depending on temperature, while the WSM5 uses a
457 critical value of ice mixing ratio (depending on air density) and a maximum allowed ice
458 crystal mass (following Rutledge and Hobbs, 1983) that suppresses the process at low
459 temperatures because of the effect of air density. Finally, the WSM5 has no dependency
460 on cloud cover for condensation processes while the Nogherotto-Tompkins scheme uses
461 cloud cover to regulate the condensation rate in the formation of stratiform clouds.

462

463 **Illustrative case studies**

464

465 Three case studies (Table 2) of Heavy Precipitation Events (HPE) have been identified in
466 order to test and illustrate the behavior of the non-hydrostatic core of the RegCM4-NH,
467 with focus on the explicit simulation of convection over different regions of the world. In
468 two test cases, California and Lake Victoria, data from the ERA-Interim reanalysis (Dee

Deleted: 1

471 et al. 2011) are used to provide initial and lateral meteorological boundary conditions for
472 an intermediate resolution run (grid spacing of 12 km, with use of convection
473 parameterizations) (Figure 3), which then provides driving boundary conditions for the
474 convection-permitting experiments. In the Texas case study, however, we nested the
475 model directly in the ERA-Interim reanalysis with boundary conditions provided every 6
476 hours, given that such configuration was able to reproduce accurately the HPE intensity.
477 In this case the model uses a large LBC relaxation zone which allows the description of
478 realistic fine-scale features driving this weather event (even if not fully consistent with the
479 Matte et al. (2017) criteria). All simulations start 24-48 hours before the HPE. The analysis
480 focuses on the total accumulated precipitation over the entire model domain at 3 km
481 resolution (Fig. 3) for the periods defined in Table 2. In the cases of California and Texas
482 the evaluation also includes the time series of 6 hourly accumulated precipitation
483 averaged on the region of maximum precipitation (black rectangles in Figs. 3) against
484 available high temporal resolution observations (NCEP/CPC) (Table 3). The discussion
485 of the case studies is presented in the next sections; the configuration files (namelists)
486 with full settings for the three test cases are available at
487 <https://zenodo.org/record/5106399>.

489 A key issue concerning the use of CP-RCMs is the availability of very high resolution,
490 high quality observed datasets for the assessment and evaluation of the models, which
491 is not there for most of the world regions. Precipitation measurements come from
492 essentially three distinct sources: in-situ rain-gauges, ground radar and satellite. In the
493 present study we use 7 observational datasets depending on the case study and the area
494 covered, as described in Table 2. We have used: Precipitation Estimation from Remotely
495 Sensed Information using Artificial Neural Networks - Climate Data Record (PERSIAN-
496 CDR), Climate Hazards Group InfraRed Precipitation with Station data (CHIRPS), the
497 Climate Prediction Center morphing method (CMORPH), Tropical Rainfall Measuring
498 Mission (TRMM), NCEP/CPC-Four Kilometer Precipitation Set Gauge and Radar
499 (NCEP/CPC), CPC-Unified daily gauge based precipitation estimates (CPC) and
500 Parameter-elevation Regressions on Independent Slopes Model (PRISM) (Table 3).
501 NCEP/CPC is a precipitation analysis which merges a rain gauge dataset with radar
502 estimates. CMORPH and PERSIAN-CDR are based on satellite measurements, CHIRPS
503 incorporates satellite imagery with in-situ station data. CPC is a gauge-based analysis of
504 daily precipitation and the PRISM dataset gathers climate observations from a wide range

544

545 **California**

546 The first case, referred to as CAL (California) in Table 2, is a HPE which occurred on 16–
 547 18 February 2004, producing flooding conditions for the Russian River, a southward-
 548 flowing river in the Sonoma and Mendocino counties of northern California (red-dot)
 549 (Figure 3). The event is documented in detail by Ralph et al. (2006), who focused their

Deleted: f
 Deleted: 2

556 attention on the impact of narrow filament-shaped structures of strong horizontal water
557 vapor transport over the eastern Pacific Ocean and the western U.S. coast, called
558 Atmospheric Rivers (ARs). ARs are typically associated with a low-level jet stream ahead
559 of the cold front of extratropical cyclones (Zhu and Newell 1998; Dacre et al. 2015; Ralph
560 et al. 2018), and can induce heavy precipitation where they make landfall and are forced
561 to rise over mountain chains (Gimeno et al. 2014). The CAL event consists of a slow
562 propagating surface front arching southeastward towards Oregon and then
563 southwestward offshore of California (Fig.3a,c). Rain began over the coastal mountains
564 of the Russian River watershed at 0700 UTC, 16 February, as a warm front descended
565 southward, and also coincided with the development of orographically favoured low-level
566 upslope flow Ralph et al. (2006).

589 levels and a parameterization for deep convection based on the Kain–Fritsch scheme
590 (Kain, 2004). The ERA-Interim driven simulation is initialized at 0000 UTC, 15 February
591 2004 (Table 2) and lasts until 0000 UTC 19 February 2004. This simulation drives a
592 corresponding RegCM4-NH run using a smaller domain centered over northern California
593 (Fig. 3a) at 3 km horizontal grid spacing and 41 vertical levels, with boundary conditions
594 updated at 6 hour intervals. In RegCM4-NH only the shallow convection component of
595 the Tiedtke scheme (Tiedtke, 1996) is activated. Simulated precipitation is compared with
596 the CHIRPS, CMORPH, TRMM, PRISM, NCEP/CPC observations described in Table 3.
597 First, we notice that the synoptic conditions characteristic of this case study, which are
598 fed into the RegCM4-NH model, are well reproduced by RegCM4 at 12 km, as shown in
599 Figure 4, where we compare the mean sea level pressure (mslp), surface temperature
600 and wind direction on 14 Feb at 7:00 am, as simulated by RegCM at 12 km (Fig.3b) with
601 corresponding fields from the ERA5 reanalysis (Fig.4a). The surface analysis of pressure
602 and fronts, derived from the operational weather maps prepared at the National Centers
603 for Environmental Prediction, Hydrometeorological Prediction Center, National Weather
604 Service (https://www.wpc.ncep.noaa.gov/dailywxmap/index_20040216.html) is also
605 reported in Figure 4c.
606 The observed precipitation datasets show similar patterns for the total accumulated
607 precipitation (Figure 5), in particular CHIRPS, PRISM and NCEP exhibit similar spatial
608 details and magnitudes of extremes. CHIRPS places a maximum around 42°N which is
609 not found in the other datasets. CMORPH and TRMM show lower precipitation maxima
610 and lesser spatial details due to their lower resolution, indicating that the performance of
611 satellite-based products may be insufficient as a stand alone product to validate the model
612 for this case.

640 In general, the observed precipitation datasets place the highest maxima on the terrain
641 peaks, with extreme rainfall greater than 250 mm in 60 hours over the coastal mountains
642 and greater than 100 – 175 mm elsewhere, (Fig. 5a). The black box in Fig 5 shows the
643 area of the Russian River watershed, highlighting the locations of the observing systems,
644 including Cazadero (CZD) and Bodega Bay (BBY) where the largest rainfall rates were
645 detected, 269 mm and 124 mm in 60-h accumulated rainfall between 0000 UTC 16
646 February and 1200 UTC 18 February 2004, respectively (Ralph et al., 2006).

647 The convection-permitting simulation captures the basic features of the observed
648 precipitation, as shown for example in Fig.5, both in terms of spatial distribution and
649 temporal evolution of rainfall (Fig.6a). However, it shows higher precipitation rates than
650 observed over the sea and over the mountain chains, with lower intensities than observed
651 in the south-east part of the mountain chain (Fig.5). By contrast, the 12-km simulation
652 severely underestimates the magnitude of the precipitation event (Fig.5).

653 Concerning the timing and intensity of the event in the CZD subregion, 6-hourly
654 accumulated precipitation (Fig.6a) averaged over the black box of Figure 5, shows that
655 both the 3 km and 12 km simulations capture the onset of the event, but the peak intensity
656 is strongly underestimated by the 12 km run, while it is well simulated by the 3 km run,
657 although the secondary maximum is overestimated. Therefore, our results demonstrate
658 that only the high resolution convection-permitting model captures this extreme event,
659 and that parameterized convection has severe limits in this regard (Done et al. 2004; Lean
660 et al. 2008; Weisman et al. 2008; Weusthoff et al. 2010; Schwartz 2014; Clark et al. 2016).

707 Texas

708 Case 2, hereafter referred to as TEX (Table 2), is a convective precipitation episode
 709 exhibiting characteristics of the “Maya Express” flood events, linking tropical moisture
 710 plumes from the Caribbean and Gulf of Mexico to midlatitude flooding over the central
 711 United States (Higgins 2011). During the TEX event, an upper-level cutoff low over
 712 northeastern Texas, embedded within a synoptic-scale ridge, moved slowly
 713 northeastward. Strong low-level flow and moisture transport from the western Gulf of
 714 Mexico progressed northward across eastern Texas. The event was characterized by
 715 low-level moisture convergence, weak upper-level flow, weak vertical wind shear, and

Deleted: 1

721 relatively cold air (center of cutoff low), which favored the slow-moving convective storms
 722 and nearly stationary thunderstorm outflow boundaries. The main flooding event in
 723 eastern Texas occurred on June 10, 2010, with a daily maximum rainfall of 216.4 mm of
 724 the region in the **black** box of Figure 7. (Higgins 2011).

As for the California case, the observed precipitation datasets show coherent patterns for the total accumulated precipitation (Fig. 6), with the highest values related to the mesoscale convective system in eastern Texas (~ 200 mm), and another smaller area of high precipitation more to the north, approximately over Oklahoma. PRISM and NCEP capture similar spatial details and magnitudes of extremes, CHIRPS has lower precipitation extremes in the north compared to the other datasets, while CMORPH and TRMM show the lowest precipitation extremes and reduced spatial details as already noted for the California case.

The bottom panels in Figure 7 present precipitation as produced by the RegCM4-NH and the ERA-Interim reanalysis (driving data), respectively. ERA-Interim reproduces some of the observed features of precipitation, but with a substantial underestimation over the areas of maximum precipitation because of its coarse resolution. By comparison, the RegCM4-NH simulation (Fig. 7) shows an improvement in both pattern and intensity of precipitation, and is substantially closer to observations over eastern Texas. However, the precipitation area is slightly overestimated and the model is not capable of reproducing the small region of maximum precipitation in the north.

The time series of precipitation over eastern Texas from 9 to 12 June 2010 for observations (black line), ERA-Interim (blue line) and RegCM4-NH (red line) are reported in Figure 6b. Precipitation increases over this region from 00:00, 10 June, until it reaches

810 the observed maximum at 12:00, 10 June (~35 mm), gradually decreasing afterwards
811 until 6:00, 11 June. The RegCM4-NH simulation shows a more realistic temporal
812 evolution than the ERA-Interim, which exhibits an overall underestimation [of precipitation](#).
813 In general, the non-hydrostatic model produces precipitation values close to the
814 observations, however, the simulated maximum is reached 6 hours earlier than observed.

815

816

817 **Lake Victoria**

818 Case 3 focuses on Lake Victoria (LKV), with the purpose of testing RegCM4-NH on a
819 complex and challenging region in terms of convective rainfall. It is estimated that each
820 year 3,000-5,000 fishermen perish on the lake due to nightly storms (Red Cross, 2014).

821 In the Lake Victoria basin, the diurnal cycle of convection is strongly influenced by
822 lake/land breezes driven by the thermal gradient between the lake surface and the
823 surrounding land. As the land warms during the course of the day, a lake breeze is
824 generated which flows from the relatively cooler water towards the warmer land surface.

825 The circulation is effectively reversed at night, when the land surface becomes cooler
826 than the lake surface, leading to convergence over the lake and associated thermal
827 instability.

828 In the LKV region, prevailing winds are generally easterly most of the year with some
829 variability due to the movement of the ITCZ. The local diurnal circulation created by the
830 presence of the lake within the larger scale easterly wind field creates two diurnal rainfall
831 maxima. During daylight hours, when the lake breeze begins to advance inland,
832 convergence is maximized on the eastern coast of the lake as the lake breeze interacts
833 with the prevailing easterlies. Studies have also noted the importance of downslope

834 katabatic winds along the mountains to the east of the lake in facilitating convergence
835 along the eastern coastal regions (Anyah et al. 2006). This creates a maximum in rainfall
836 and convection on the eastern coast of LKV. Conversely, during nighttime hours, when
837 the local lake circulation switches to flow from the land towards the lake, the prevailing
838 easterlies create locally strong easterly flow across the lake and an associated maximum
839 in convergence and rainfall on the western side of LKV.

840 The LKV simulation starts on 25 November 1999 and extends to the beginning of
841 December 1999 (Table 2), covering a 5-day period which falls within the short-rain season
842 of East Africa. The choice of 1999, an ENSO neutral year, was made in order to focus the
843 analysis on local effects, such as the diurnal convection cycle in response to the lake/land
844 breeze, with no influence of anomalous large scale conditions. A 1-dimensional lake
845 model (Hostetler et al. 1993; Bennington et al. 2014) interactively coupled to RegCM4-
846 NH was utilized to calculate the lake surface temperature (LST), since lake-atmosphere
847 coupling has been shown to be important for the LKV (Sun et al. 2015; Song et al. 2004).
848 This coupled lake model has been already used for other lakes, including Lake Malawi in
849 southern Africa (Diallo et al. 2018). As with the other experiments, the boundary
850 conditions are provided by a corresponding 12 km RegCM4 simulation employing the
851 convection scheme of Tiedtke (1996).

852 At the beginning of the simulation, the LST over the lake is uniformly set to 26C, and is
853 then allowed to evolve according to the lake-atmosphere coupling. [This initial LST value](#)
854 [is based on previous studies. For example, Talling \(1969\) finds Lake Victoria surface](#)
855 [temperatures ranging from 24.5-26°C during the course of the year. Several studies have](#)
856 [used RCMs to investigate the Lake Victoria climate \(Anyah et al., 2006; Anyah and](#)

Deleted: 1

858 [Semazzi 2009, Sun et al. 2015](#)), and found a significant relationship between lake
859 temperature and rainfall depending on season. The value of 26°C is typical of the winter
860 season and was chosen based on preliminary sensitivity tests using different values of
861 initial temperature ranging from 24°C to 26°C.

862 The synoptic feature favorable for the production of precipitation over the LKV in this
863 period corresponds to a large area of southeasterly flow from the Indian Ocean (Fig. 8a),
864 which brings low-level warm moist air into the LKV region facilitating the production of
865 convective instability and precipitation. This synoptic situation, with a low-level
866 southeasterly jet off the Indian Ocean, is a common feature associated with high
867 precipitation in the area (Anyah et al. 2006) is found in ERA5 (Figure 7a).

Figure 8: Mean sea level pressure (mslp) (white black contour lines), surface temperature (color shading) and 100-m wind direction (black arrows) averaged over the period 25 November 00:00 - 1 December 00:00, of ERA5 reanalysis (a) and RegCM 12km (b). The black line (b) shows the cross-section position represented in Fig. 9

The LKV region dynamics are quite distinct between nighttime and daytime and the rainfall in and around the lake has a pronounced diurnal cycle. To understand this strong diurnal cycle, Figure 9 shows a cross-section through the lake (32E to 34E, black line in right panel of Fig. 8) along 1S latitude at a period during strong nighttime (Fig. 9b,d; 6Z 30 November) and daytime convection (Fig. 9a,c; 12Z 29 November). During the day,

924 surface heating around the lake leads to a temperature differential between the land and
 925 lake sufficient to generate a lake breeze, which causes divergence over the lake, while
 926 over the surrounding highlands the environment is more conducive to convection (9a,c).
 927 Conversely, during the night, a land breeze circulation is generated, which induces
 928 convergence and convection over the lake, (Figure 9b,d).

929 Comparing the 3 km simulation to the 12 km forcing run, we find that the localized
 930 circulations created by local forcings (i.e. convection) are much stronger in the high
 931 resolution experiment. We also find stronger and more localized areas of convective
 932 updrafts as seen in the vertical velocities (9a,b) compared to the 12 km simulation (8c,d;
 933 omega is shown instead of vertical velocity here because of the difference in model
 934 output). The stronger convection simulated in the 3 km experiment is also tied to the
 935 stronger temperature gradients between lake and land and between day and night (Figure
 936 10).

937 This demonstrates that the 3km simulation is better equipped to simulate the localized
 938 circulations associated with this complex land-lake system.

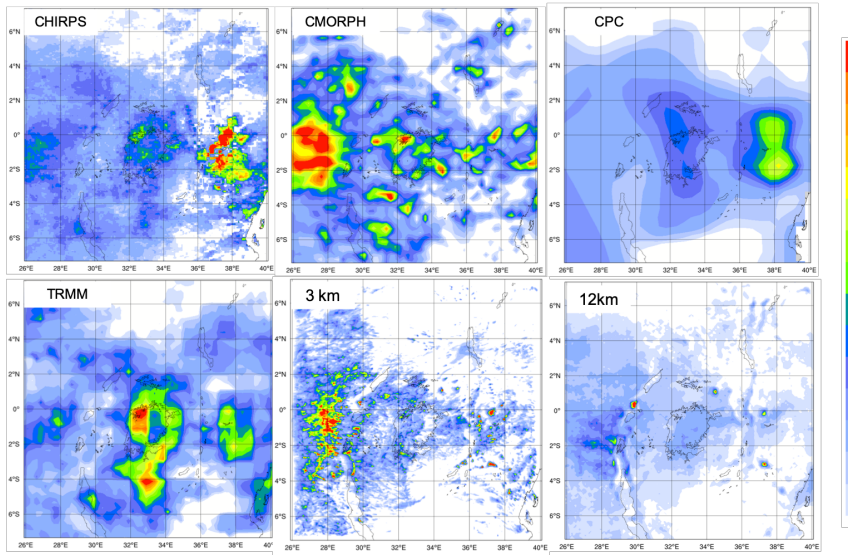

Figure 11: Total accumulated precipitation during the LKV case measured by CHIRPS (top left), CMORPH (top center), CPC (top right) TRMM (bottom left) and calculated by RegCM4 at 3 km (bottom center) and 12 km (bottom right).

Figure 11, finally reports, the total accumulated precipitation observed and simulated for the LKV case. TRMM and CPC show a similar pattern, with two-rainfall maxima of different intensities over the southeastern and northwestern lake areas. CMORPH shows a western rainfall maximum similar to TRMM and one large rainfall area almost entirely centered over the highlands to the west of the lake. Conversely in CHIRPS, a maximum is found to the east of the lake while several localized maxima occur over the lake. The differences between the observed datasets highlight the issue of observational uncertainty and the need to take into consideration shortcomings associated with the types of observational datasets considered. Different datasets can have significantly

1025 different climatology, especially in areas of low data availability. For example, Prein and
1026 Gobiet (2017) analyzed two gauge-based European-wide datasets, and seven global low-
1027 resolution datasets, and found large differences across the observation products, often
1028 of similar magnitude as the difference between model simulations. In this case and for
1029 this area the observation uncertainty plays a big role especially at high resolution, and
1030 highlights the need for an adequate observational network for model validation.

1031 However, even taking into account the elevated uncertainty existing in the observations
1032 datasets, we find a significant underestimation of rain amounts in the 12 km run (Fig 11),
1033 with a wide area of rainfall around 80mm over the whole of LKV. In contrast, the 3 km
1034 simulation shows substantially greater detail, with rainfall patterns more in agreement with
1035 the CMORPH observations. In particular, the 3 km simulation reproduces well the local
1036 rainfall maxima on the western side of the lake, although these appear more localized
1037 and with a multi-cell structure compared to CMORPH and TRMM. Additionally, the 12
1038 km simulation underestimates the observed heavy rainfall totals in the highlands to the
1039 west of the lake region, which are instead reproduced by the 3 km simulation.

1040 This last test case demonstrates the ability of RegCM4-NH in simulating realistic
1041 convective activity over a morphologically complex region, which is a significant
1042 improvement compared to the hydrostatic-coarse resolution model configuration.

1044 Conclusions and future outlook

1045 In this paper we have described the development of RegCM4-NH, a non hydrostatic
1046 version of the regional model system RegCM4, which was completed in response to the
1047

Deleted: shows that the total observed rainfall for the period is characterized by diurnal rainfall maxima associated with the local lake circulation. In particular, the north-western side of the lake shows a rainfall maximum exceeding 250mm during the 5-day simulation, while most of the north-west portion of the lake shows over 150mm in total rainfall. In addition, a weaker but still significant rainfall maximum is seen on the inland south-eastern coast of LKV.

1096 need of moving to simulations at convection-permitting resolutions of a few km. The
1097 dynamical core of the non-hydrostatic version of MM5 has been thus incorporated into
1098 the RegCM4 system, an approach facilitated by the fact that the this last is essentially an
1099 evolution of the MM5. Some modifications to the MM5 dynamical core were also
1100 implemented to increase the model stability for long term runs. RegCM4-NH also includes
1101 two explicit cloud microphysics schemes needed to explicitly describe convection and
1102 cloud processes in the absence of the use of cumulus convection schemes. Finally, we
1103 presented a few case studies of explosive convection to illustrate how the model provides
1104 realistic results in different settings and general improvements compared to the coarser
1105 resolution hydrostatic version of RegCM4 for such types of events.

1106

1107 As already mentioned, RegCM4-NH is currently being used for different projects, and
1108 within these contests, is being run at grid spacings of a few km for continuous decadal
1109 simulations, driven by reanalyses of observations or GCM boundary conditions (with the
1110 use of an intermediate resolution domains) over different regions, such as the Alps, the
1111 Eastern Mediterranean, Central-Eastern Europe and the Caribbeans. These projects,
1112 involving multi-model intercomparisons, indicate that the performance of RegCM4-NH is
1113 generally in line with that of other convection permitting models, and exhibits similar
1114 improvements compared to coarser resolution models, such as a better simulation of the
1115 precipitation diurnal cycle and of extremes at hourly to daily time scales. The results
1116 obtained within the multi-model context confirm previous results from single-model
1117 studies (Kendon et al. 2012, 2017, Ban et al. 2014, 2015; Prein et al. 2015, 2017), but
1118 also strengthen the robustness of the findings through reduced uncertainty compared to
1119 coarse resolution counterpart (Ban et al., 2021, Pichelli et al., 2021). The convection-
1120 permitting scale can thus open the perspective of more robust projections of future
1121 changes of precipitation, especially over short time scales.

1122

1123

1124 One of the problems of the RegCM4-NH dynamical core is that, especially for long runs
1125 with varied meteorological conditions, a relatively short time step needs to be used for
1126 stability reasons. This makes the model rather computationally demanding, although not

Deleted: Towards this goal we have incorporated into the RegCM4 framework Tt

Deleted: from

Deleted: RegCM system

Deleted: , as described in section 2

Deleted: RegCM4-NH is currently being used for different projects, such as the Flagship Pilot Study on convection permitting modeling (Coppola et al. 2020, Ban et al. 2021, Pichelli et al. 2021) and the EUCP EU project (Hewitt and Lowe 2018). In these contexts, the model is being run at grid spacings of a few km for continuous decadal simulations, both driven by reanalyses of observations and GCM fields (in both cases with the use of an intermediate resolution run to act as interface) over different regions, such as the Alps, the Eastern Mediterranean, Central-Eastern Europe and the Caribbeans. This will help better validate and understand the model behavior at these high resolutions....

1146 more than other convection-permitting modeling systems such as the Weather Research
1147 and Forecast model (WRF, Skamarok et al. 2008). For this reason, we are currently
1148 incorporating within the RegCM system a very different and more computationally efficient
1149 non-hydrostatic dynamical core, which will provide the basis for the next version of the
1150 model, RegCM5, to be released in the future.

Deleted:

1151
1152 Following the philosophy of the RegCM modeling system, RegCM4-NH is intended to be
1153 a public, free, open source community resource for external model users. The non-
1154 hydrostatic dynamical core has been implemented in a way that it can be activated in
1155 place of the hydrostatic dynamics through a user-set switch, which makes the use of
1156 RegCM4-NH particularly simple and flexible. We therefore envision that the model will be
1157 increasingly used by a broad community so that a better understanding can be achieved
1158 of its behavior, advantages and limitations.
