

23 QMG (Qingmuguan) model. The structural design of this model is relatively simple, and it is
24 generally divided into surface and underground double-layered structures. The parameters
25 that represent the structural functions of each layer have clear physical meanings, and the
26 parameters are less than those of the current distributed models. This allows modeling in
27 karst areas with only a small amount of necessary hydrogeological data. 18 flood processes
28 across the karst underground river in the Qingmuguan karst trough valley are simulated by
29 the QMG model, and the simulated values agree well with observations, for which the
30 average value of Nash–Sutcliffe coefficient was 0.92. A sensitivity analysis shows that the
31 infiltration coefficient, permeability coefficient, and rock porosity are the parameters that
32 require the most attention in model calibration and optimization. The improved
33 predictability of karst flooding by the proposed QMG model promotes a better mechanistic
34 depicting of runoff generation and confluence in karst trough valleys.

36 (Qingmuguan) model; Parametric optimization; Parameter sensitivity analysis

37 1 Introduction

38 Karst trough and valley landforms~~Karst trough valleys~~ are very common in China,
39 especially in the southwest. In general, these karst areas are water scarce during most of
40 the year because their surfaces store very little rainfall, but they are also potential birthplaces
41 for floods because trough and valley landforms and topographic features facilitate the
42 formation and propagation of floods (White, 2002; Li et al., 2021). The coexistence of
43 drought and flood is a typical phenomenon in these karst trough and valley areas. Taking the
44 example of the present study area, i.e. the Qingmuguan karst trough valley, floods used to
45 happen here constantly during the rainy season. In recent years, with more extreme rainfall
46 events and the increased area of construction land in the region, rainfall infiltration has

47 decreased and rapid runoff over impervious surfaces has increased, resulting in frequent
48 catastrophic flooding in the basin (Liu et al., 2009). Excess water overflows from karst
49 sinkholes and underground river outlets often occur during floods ([Jourde et al., 2007, 2014;](#)
50 [Martinotti et al., 2017](#)), flooding large areas of farmland and residential areas and causing
51 serious economic losses ([Gutierrez, 2010; Parise, 2010;](#) Yu et al., 2020). Therefore, it is both
52 important and urgent to simulate and predict karst flooding events in karst trough and
53 valleys such as the study area.

54 Hydrological models can be effective for forecasting floods and evaluating water
55 resources in karst areas ([Bonacci et al., 2006;](#) Ford and Williams, 2007; Williams, [2008,](#)
56 2009). However, modelling floods in karst regions is extremely difficult because of the
57 complex hydrogeological structure. Karst water-bearing systems consist of multiple media
58 under the influence of complex karst development dynamics (Worthington et al., 2000;
59 Kovács and Perrochet, 2008; [Gutierrez, 2010](#)), such as karst caves, conduits, fissures and
60 pores, and are usually highly spatially heterogeneous (Chang and Liu, 2015;
61 [TeixeiraparenteMarie et al., 2019](#)). In addition, the intricate surface hydrogeological
62 conditions and the hydrodynamic conditions inside the karst water-bearing medium result in
63 significant temporal and spatial differences in the hydrological processes in karst areas
64 (Geyer et al., 2008; Bittner et al., 2020).

65 In early studies of flood forecasting in karst regions, simplified lumped hydrological
66 models were commonly used to describe the rainfall–discharge relationship (e.g. Kovács and
67 Sauter, 2007; Fleury et al., 2007b; Jukić and Denić, 2009; Hartmann et al., 2014a). With the
68 development of physical exploration technology and the progress made in mathematics,
69 computing and other interdisciplinary disciplines, the level of modelling has gradually
70 improved (Hartmann and Baker, 2017; Hartmann, 2018; Petrie et al., 2021), and distributed
71 hydrological models have subsequently become widely used in karst areas. The main
72 difference between lumped and distributed hydrological models is that the latter divide the
73 entire basin into many sub-basins to calculate the runoff generation and confluence, thereby
74 better describing the physical properties of the hydrological processes inside the karst
75 water-bearing system ([Jourde et al., 2007;](#) Hartmann, 2018; Epting et al., 2018).

76 Because of their simple structure and little demand for modelling data, lumped
77 hydrological models have been used widely in karst areas (Kurtulus and Razack, 2007;
78 Ladouche et al., 2014). In a lumped model, the river basin is considered as a whole to
79 calculate the runoff generation and confluence, and there is no division running into
80 sub-basins (Dewandel et al., 2003; Bittner et al., 2020). Lumped models usually consider the
81 inputs and outputs of the model (Liedl and Sauter, 2003; Hartmann and Bake, 2013, 2017).
82 In addition, most of the model parameters are not optimized in a lumped model, and the
83 physical meaning of each parameter is unclear (Chen, 2009; Bittner et al., 2020).

84 Distributed hydrological models are of active interest in flood simulation and
85 forecasting research (Ambroise et al., 1996; Beven and Binley, 2006; Zhu and Li, 2014).
86 Compared with a lumped model, a distributed model has a more definite physical
87 significance for the model structure in terms of its mechanism (Meng and Wang, 2010;
88 Epting et al., 2018). In a distributed hydrological model, an entire karst basin can be divided
89 into many sub-basins (Birk et al., 2005) using high-resolution digital elevation map (DEM)
90 data. In the rainfall-runoff algorithm of the model, the hydrogeological conditions and karst
91 aquifer characteristics can be considered fully to simulate precisely the runoff generation
92 and confluence ([Martinotti et al., 2017](#); Gang et al., 2019). The commonly used basin
93 distributed hydrological models (i.e. not a special groundwater numerical model such as
94 MODFLOW) have also been applied widely in karst areas and include the SHE/MIKE SHE
95 model (Abbott et al., 1986a,b; Doummar et al., 2012), SWMM model (Peterson and Wicks,
96 2006; Blansett and Hamlett, 2010; Blansett, 2011), TOPMODEL (Ambroise et al., 1996;
97 Suo et al., 2007; Lu et al., 2013; Pan, 2014) and SWAT model (Peterson and Hamlett, 1998;
98 Ren, 2006).

99 The commonly used distributed hydrological models have multiple structures and
100 numerous parameters (Lu et al., 2013; Pan, 2014), which means that a distributed model
101 may need vast amounts of data to build its framework in karst regions. For example, the
102 distributed groundwater model MODFLOW-CFPM1 requires detailed data regarding the
103 distribution of karst conduits in a study area (Reimann et al., 2009). Another example is the
104 Karst-Liuxihe model (Li et al., 2019), ~~which has there are fifteen parameters and five~~

105 | underground vertical ~~structures~~layers in the model. ~~structure and has 15 parameters, thereby~~
106 | ~~Such a complex structure makes the modeling data demand is large, and the modeling in~~
107 | ~~karst area is extremely difficult, making it difficult to model in karst areas.~~ In addition, a
108 | special borehole pumping test may be required to obtain the rock permeability coefficient.

109 | To overcome the difficulty of the large modelling-data demands for distributed
110 | hydrological models in karst areas, a new physically based distributed hydrological
111 | model—known as the QMG (Qingmuguan) model-V1.0—was developed in the present
112 | study. Other commonly used karst groundwater models with complex structure and
113 | parameters—such as the aforementioned MODFLOW-CFPM1 model—require a lot of
114 | hydrogeological data for modelling in karst areas (Qin and Jiang, 2014). The new QMG
115 | model has a high potential for application in karst hydrological simulation and forecasting. It
116 | has certain advantages in its framework and structural design, having a double-layer
117 | structure and fewer parameters. The horizontal structure is divided into river channel units
118 | and slope units, and the vertical structure below the surface is divided into a shallow karst
119 | aquifer and a deep karst aquifer system. This relatively simple model structure reduces the
120 | demand for modelling data in karst areas, and only a small amount of hydrogeological data
121 | is needed for modelling.

122 | ~~To ensure that the QMG model work well in karst flood simulation and prediction in the~~
123 | ~~case of relatively simple structure and parameters. We carefully designed the algorithms of~~
124 | ~~runoff generation and confluence in the model.~~ To ensure that the QMG model works well in
125 | karst flood simulation and prediction despite its relatively simple structure and parameters,
126 | we carefully designed the algorithms for runoff generation and confluence in the model.
127 | Also, to verify the applicability of the QMG model to flood simulation in karst basins, we
128 | selected the Qingmuguan karst trough valley in Chongqing, China as the study area for a
129 | flood simulation and uncertainty analysis. In particular, we analysed the sensitivity of the
130 | model parameters.

131 2 Study area and data

132 2.1 Landform and topography

133 The Qingmuguan karst trough valley is located in the southeastern part of the Sichuan Basin,
134 China at the junction of the Beibei and Shapingba districts in Chongqing, with the
135 coordinates of 29°40'N–29°47'N, 106°17'E–106°20'E. The basin covers an area of 13.4 km²
136 and is part of the southern extension of the anticline at Wintang Gorge in the Jinyun
137 Mountains, with the anticlinal axis of Qingmuguan located in a parallel valley in eastern
138 Sichuan (Yang et al., 2008). The surface of the anticline is heavily fragmented, and faults
139 are extremely well developed with large areas of Triassic carbonate rocks exposed. Under
140 the long-term erosion of karst water, a typical karst ~~trough~~ landforms ~~pattern of 'three~~
141 ~~mountains and two troughs'~~ has formed (Liu et al., 2009). This karst trough landform
142 provides convenient conditions for flood propagation, and the development of karst
143 landforms is extremely common in the karst region of southwest China, especially in the
144 karst region of Chongqing. ~~Similar regions include the karst trough valley of the Zhongliang~~
145 ~~Mountains and the Laolongdong karst basin in Nanshan, Chongqing.~~

146 The basin is oriented ~~north-north-east and south-south-west~~ in a narrow band of slightly
147 curved arcs and is ~12 km long from north to south. ~~The direction of the mountains in the~~
148 ~~region is basically the same as that of the tectonic line. The direction of the mountains in the~~
149 ~~region is generally consistent with the direction of the tectonic line. The difference in~~
150 ~~relative elevation is 200–300 m.~~ The map in ~~Figure-~~ 1 gives an overview of the Qingmuguan
151 karst basin.

152 **Figure 1.** The Qingmuguan karst basin.

153 2.2 Hydrogeological conditions

154 The Qingmuguan basin is located within the subtropical humid monsoon climate zone, with
155 an average temperature of 16.5 °C and an average precipitation of 1250 mm ~~that is~~
156 concentrated mainly in May–September. An underground river system has developed in the

157 karst trough valley, with a length of 7.4 km, and the water supply of the underground river is
158 mainly rainfall recharge (Zhang, 2012). Most of the precipitation is collected along the hill
159 slope into the karst depressions at the bottom of the trough valley, where it is recharged to
160 the underground river through the dispersed infiltration of surface karst fissures and
161 ~~concentrated injection from~~ sinkholes (Fig. 1a). An upstream surface river collects in a
162 gentle valley and enters the underground river through the Yankou sinkhole (elevation
163 524 m). Surface water in the middle and lower reaches of the river system enters the
164 underground river system mainly through ~~eatenuiform cover collapse~~ sinkholes (Gutierrez
165 ~~et al., 2014~~) or fissures.

166 The stratigraphic and lithologic characteristics of the basin are dominated largely by
167 carbonate rocks of the Lower Triassic Jialingjiang Group (T_{1j}) and Middle Triassic Leikou
168 Slope Group (T_{2l}) on both sides of the slope, with some quartz sandstone and mudstone
169 outcrops of the Upper Triassic Xujiahe Group (T_{3xj}) (Zhang, 2012). The topography of the
170 basin presents a general anticline (Fig. 1b), where carbonate rocks on the surface are
171 corroded and fragmented, ~~high permeability with a large permeability coefficient~~. Compared
172 with the core of the anticline, the ~~shale rocks of the two wings of~~ the anticline are less
173 eroded and form a good waterproof layer.

174 To investigate the distribution of karst conduits in the underground river system, we
175 conducted a tracer test in the study area. The tracer was placed into the Yankou sinkhole and
176 recovered in the Jiangjia spring (Fig. 1a,c). According to the tracer test results (Gou et al.,
177 2010), the karst water-bearing medium in the aquifer was anisotropic, ~~whereas the soluble~~
178 ~~carbonate rocks were extremely permeable. and The the~~ karst conduits in the underground
179 river were extremely well developed, and there was a large single-channel underground river
180 ~~about five meters wide~~. The response of the underground river to rainfall was very fast, with
181 the peak flow observed at the outlet of Jiangjia spring 6–8 h after rainfall ~~based on the tracer~~
182 ~~test results~~. The flood peak rose quickly and the duration of the peak flow was short. The
183 underground river system in the study area is dominated by large karst conduits, which is not
184 conducive to water storage in water-bearing media, but is very conducive to the propagation
185 of floods.

186 2.3 Data

187 To build the QMG model to simulate the karst flood events, the necessary modelling
188 baseline data had to be collected, including: 1) high-resolution DEM data and
189 hydrogeological data (e.g., the thickness of the epikarst zone, rainfall infiltration coefficient
190 on different karst landforms, and permeability coefficient of rock); 2) land-use and soil type
191 data; and 3) rainfall data in the basin and water flow data of the underground river. The
192 DEM data was downloaded from a free database on the public Internet, with an initial spatial
193 resolution of 30×30 m. The spatial resolution of landuse and soil types were 1000×1000
194 m, and they were also downloaded from the Internet. After considering the applicability of
195 modelling and computational strength, as well as the size of the basin in the study area (13.4
196 km^2), the spatial resolution of the three types of data was resampled uniformly in the QMG
197 model and downscaled to 15×15 m based on a spatial discrete method by Berry et. (2010).

198 The hydrogeological data necessary for modelling was obtained in three simple ways. 1)
199 A basin survey was conducted to obtain the thickness of the epikarst zone, which was
200 achieved by observing the rock formations on hillsides following cutting for road
201 construction. Information was collected regarding the location, general shape, and size of
202 karst depressions and sinkholes, which had a significant impact on compiling the DEM data
203 and determining the convergence process of surface runoff. And the sinkholes in the basin
204 are cover collapse sinkholes (Gutierrez et al., 2014) according to the basin survey. There are
205 3 large sinkholes (more than 3 meters in diameter) and 12 small sinkholes less than 1 meter
206 in diameter. The rest of the sinkholes between 1 and 3 meters in diameter are 5 in total.
207 The confluence calculation of these sinkholes in the model was based on the results of
208 previous study (Meng et al., 2009). 2) Empirical equations developed for similar basins were
209 used to obtain the rainfall infiltration coefficient for different karst landforms and the
210 permeability coefficient of rock. For example, the rock permeability coefficient was
211 calculated based on an empirical equation from a pumping test in a coal mine in the study
212 area (Li et al., 2019). 3) A tracer experiment was conducted in the study area (Gou et al.,
213 2010) to obtain information on the underground river direction and flow velocity. for

214 instance, underground karst conduits are well developed in the area, which form an
215 underground river about five meters wide. There is no hydraulic connection between the
216 underground river system in the area and the adjacent basin, means there is no overflow
217 recharge.

218 Rainfall and flood data are important model inputs, and represent the driving factors
219 that allow hydrological models to operate. In the study area, rainfall data was acquired by
220 two rain gauges located in the basin (Fig. 1a). Point rainfall was then spatially interpolated
221 into basin-level rainfall (for such a small basin area rainfall results obtained from two rain
222 gauges was considered representative). There were 18 karst flood events in the period of 14
223 April 2017 to 10 June 2019. We built a rectangular open channel at the underground river
224 outlet and set up a river gauge on it (Fig. 1a) to record the water level and flow data every 15
225 minutes.

226 **3 Methodology**

227 **3.1 Hydrological model framework and algorithms**

228 The hydrological model developed in this study was named the QMG model after the basin
229 for which it was developed and to which it was first applied, i.e. the Qingmuguan basin. The
230 QMG model ~~proposed in this study~~ has a two-layer structure, including a surface part and an
231 underground part, ~~with the~~ The former surface structure mainly performing the calculation
232 of runoff generation and the confluence of the surface river, while the underground structure
233 ~~latter~~ performs the confluence calculation of the underground river system.

234 The structure of the QMG model is divided into a two-layer structure, both horizontally
235 and vertically. The horizontal structure of the model is divided into river channel units and
236 slope units. The vertical structure below the surface is divided into a shallow karst aquifer
237 (including soil layers, karst fissures and conduit systems in the epikarst zone) and a deep
238 karst aquifer system (~~bedrock~~ rock-stratum and underground river system). This relatively
239 simple model structure means that only a small amount of hydrogeological data is needed
240 ~~when modelling~~ in karst regions. Figure 2 shows a flowchart of the modelling and
241 calculation procedures required for the QMG model.

242 **Figure 2.** Modelling flow chart of QMG (Qingmuguan) model.

243 To describe accurately the runoff generation and confluence on a grid scale, these karst
244 sub-basins are further divided into many karst hydrological response units (KHRUs) based
245 on the high-resolution (15 × 15 m) DEM data in the model. The specific steps involved in
246 the division were adopted by referring to studies of hydrological response units (HRUs) in
247 TOPMODEL by Pan (2014). As the smallest basin computing units, the KHRUs can
248 effectively ignore the spatial differences of karst development within the units and reduce
249 the uncertainty in the classification of model units. Figure 3 shows the spatial structure of
250 the KHRUs.

251 **Figure 3.** Spatial structure of karst hydrological response units (KHRUs) (Li et al., 2021).

252 The right-hand side of Figure- 3 shows a three-dimensional spatial model of KHRUs
253 established in the laboratory to reflect visually the storage and movement of water in the
254 karst water-bearing medium with each spatial anisotropy, and to provide technical support
255 for establishing the hydrological model.

256 The modelling and operation of the QMG model consists of three main stages: 1)
257 spatial interpolation, and the retention of rainfall and evaporation calculations; 2) runoff
258 generation and confluence calculation for the surface river; and 3) confluence calculation for
259 the underground runoff, including the confluence in the shallow karst aquifer and the
260 underground river system.

261 **3.1.1 Rainfall and evaporation calculation**

262 In the QMG model, the spatial interpolation of rainfall is accomplished by a kriging method
263 using the ArcGIS 10.2 software. The Tyson polygon method may be a simpler method for
264 rainfall interpolation if the number of rainfall gauges in the basin is sufficient. The point
265 rainfall observed by the two rainfall gauges in the basin (Fig. 1a) was interpolated spatially
266 into areal rainfall for the entire basin.

267 Basin evapotranspiration in the KHRUs was mainly vegetal, soil evaporation and water
268 surface evaporation. They were calculated using the following equations (modified from Li
269 et al., 2020):

$$\begin{cases}
E_v = V^{t+\Delta t} - V^t - P_v \\
E_s = \lambda E_p, \text{ if } F = F_c \\
E_s = \lambda E_p \frac{F}{F_c}, \text{ if } F < F_{\text{sat}} \\
E_w = \Delta e \cdot \left[1.12 + 0.62(\Delta T)^{0.9} \right] \cdot \left[0.084 + 0.24(1 - \gamma^2)^{1/2} \right] \cdot \left[0.348 + 0.5\omega^{1.8-1.137\omega^{0.05}} \right]
\end{cases} \quad (1)$$

271 Here, E_v [mm] is the vegetal discharge, $V^{t+\Delta t} - V^t$ [mm] is the rainfall variation by
272 vegetation interception, P_v [mm] is the vegetation interception of rainfall and E_s [mm]
273 is the actual soil evaporation. The term λ is the evaporation coefficient. The term E_p
274 [mm] is the evaporation capability, which can be measured experimentally or estimated
275 by the water surface evaporation equation E_w . The term F [mm] is the actual soil
276 moisture, F_{sat} [mm] is the saturation moisture content, F_c [mm] is the field capacity, E_w
277 [mm/d] is the evaporation of the water surface and $\Delta e = e_0 - e_{150}$ [hPa] is the draught
278 head between the saturation vapour pressure of the water surface and the air vapour
279 pressure 150 m above the water surface ~~(150 m above the water surface was selected~~
280 ~~here because the altitude for temperature and humidity observations in the southwestern~~
281 ~~karst regions of China is usually set at 150–200 m)~~. The term $\Delta T = t_0 - T_{150}$ [°C] is the
282 temperature difference between the water surface and the temperature 150 m above the
283 water surface, γ is the relative humidity 150 m above the water surface and ω [m/s]
284 is the wind speed 150 m above the water surface.

285 3.1.2 Runoff generation

286 In the QMG model, the surface runoff generation in river channel units means the rainfall in
287 the river system after deducting evaporation losses. This portion of the runoff will
288 participate in the confluence process directly through the river system, rather than
289 undergoing infiltration. In contrast, the process of runoff generation in slope units is more
290 complex, and its classification is related to the developmental characteristics of surface karst
291 in the basin, rainfall intensity and soil moisture. For example, when the soil moisture content
292 is already saturated, there is the potential for excess infiltration surface runoff in exposed
293 karst slope units. The surface runoff generation of the KHRUs in the river channel units and

294 slope units can be described by the following equations (modified from Chen, 2009, 2018;
 295 Li et al., 2020):

$$\begin{cases}
 P_r(t) = [P_i(t) - E_p] \frac{L \cdot W_{\max}}{A} \\
 R_{si} = (P_i - f_i), P_i \geq f_{\max} \\
 R_{si} = 0, P_i < f_{\max} \\
 f_{\max} = \alpha(F_c - F)^\beta + F_s
 \end{cases} \quad (2)$$

297 Here, $P_r(t)$ [mm] is the net rainfall (deducting evaporation losses) in the river channel units
 298 at time t [h], $P_i(t)$ [mm] is the rainfall in the river channel units, L [m] is the length of the
 299 river channel, W_{\max} [m] is the maximum width of the river channel selected and A [m²] is
 300 the cross-sectional area of the river channel. R_{si} [mm] is termed the excess infiltration runoff
 301 in the QMG model, when the vadose zone is short of water and has not been filled. The
 302 infiltration capacity f_{\max} is different in different karst landform units, α , β are the parameters
 303 of the Holtan model and F_s [mm] is the stable depth of soil water infiltration.

304 In the KHRUs (Fig. 3), underground runoff is generated primarily from the infiltration
 305 of rainwater and direct confluence recharge from sinkholes or skylights. In the QMG model,
 306 the underground runoff is calculated by the following equations (modified from Chen,
 307 2018):

$$\begin{cases}
 R_g = R_0 \exp(-pt^m) \\
 R_e = v_e \cdot I_w \cdot z
 \end{cases} \quad (3)$$

309 where

$$\begin{cases}
 \frac{\partial R_e}{\partial x} + I_w \cdot z \cdot \frac{\partial F}{\partial t} = R_r - R_{\text{epi}} \\
 v_e = K \cdot \tan(\alpha), F > F_c \\
 v_e = 0, F \leq F_c
 \end{cases} \quad (4)$$

311 Here, R_g [mm] is the underground runoff depth (this part of the underground runoff is mainly
 312 from the direct confluence supply of the karst sinkholes or karst windowsskylights in the
 313 study area), R_0 [mm] is the average depth of the underground runoff, p and m are attenuation
 314 coefficients calculated by conducting a tracer test in the study area, R_e [L/s] is the

315 underground runoff generated from rainfall infiltration in the epikarst zone, I_w [mm] is the
 316 width of the underground runoff on the KHRUs, z [mm] is the thickness of the epikarst zone,
 317 R_r [mm²/s] is the runoff recharge on the KHRUs during period t , R_{epi} [mm²/s] is the water
 318 infiltration from rainfall, v_e [mm/s] is the flow velocity of the underground runoff, K
 319 [mm/s] is the current permeability coefficient and α is the hydraulic gradient of the
 320 underground runoff. If the current soil moisture is less than the field capacity, i.e. $F \leq F_c$,
 321 then the vadose zone is not yet full, there will be no underground runoff generation, and
 322 rainfall infiltration at this time will continue to compensate for the lack of water in the
 323 vadose zone until it is full and before runoff is generated.

324 3.1.3 Channel routing and confluence

325 In the QMG model, the calculation of runoff confluence on the KHRUs includes the
 326 confluence of surface river channel and underground runoff. There are already many mature
 327 and classical algorithms available for calculating the runoff confluence in river channel units
 328 and slope units, such as the Saint-Venant equations and Muskingum convergence model. In
 329 this study, the Saint-Venant equations were adopted to describe the confluence in the surface
 330 river and hill slope units, for which a wave movement equation was adopted to calculate
 331 confluence in slope units (Chen, 2009):

$$332 \begin{cases} \frac{\partial Q}{\partial x} + L \frac{\partial h}{\partial t} = q \\ S_f - S_0 = 0 \end{cases} \quad (5)$$

333 where

$$334 Q = vhL = \frac{L}{n} h^{\frac{5}{3}} S_0^{\frac{1}{2}}. \quad (6)$$

335 Here, we customized two variables a and b :

$$336 \begin{cases} a = \left(\frac{n}{L} S_0^{-\frac{1}{2}}\right)^{\frac{3}{5}} \\ b = \frac{3}{5} \end{cases} \quad (7)$$

337 Equation (7) was substituted into Eq. (5) and discretized by a finite-difference method,
 338 giving

$$339 \quad \begin{cases} \frac{\partial Q}{\partial x} + abQ^{(b-1)} \frac{\partial Q}{\partial t} - q = 0 \\ \frac{\Delta t}{\Delta x} Q_{i+1}^{t+1} + a(Q_{i+1}^{t+1})^b = \frac{\Delta t}{\Delta x} Q_i^{t+1} + a(Q_{i+1}^t)^b + q_{i+1}^{t+1} \Delta t \end{cases} \quad (8)$$

340 The Newton–Raphson method was used for the iterative calculation using Eq. (8):

$$341 \quad [Q_{i+1}^{t+1}]^{k+1} = [Q_{i+1}^{t+1}]^k - \frac{\frac{\Delta t}{\Delta x} [Q_{i+1}^{t+1}]^k + a([Q_{i+1}^{t+1}]^k)^b - \frac{\Delta t}{\Delta x} Q_i^{t+1} - a(Q_{i+1}^t)^b - q_{i+1}^{t+1} \Delta t}{\frac{\Delta t}{\Delta x} + ab([Q_{i+1}^{t+1}]^k)^{b-1}}, \quad (9)$$

342 where Q [L/s] is the confluence of water flow in slope units, L [dm] is its runoff width, h
 343 [dm] is the runoff depth and q [dm²/s] is the lateral inflow on the KHRUs. Here, the friction
 344 slope S_f equals the hill slope S_0 , and the inertia term and the pressure term in the motion
 345 equation of the Saint-Venant equations were ignored. The term v [dm/s] is the flow velocity
 346 of surface runoff in the slope units as calculated by the Manning equation, n is the roughness
 347 coefficient of the slope units, Q_i^{t+1} [L/s] is the slope inflow in the KHRU at time $t+1$ and
 348 Q_{i+1}^{t+1} [L/s] is the slope discharge in the upper adjacent KHRU at time $t+1$.

349 Similarly, the surface river channel confluence was described based on the
 350 Saint-Venant equation, where a diffusion wave movement equation was adopted, meaning
 351 that the inertia term in the motion equation was ignored:

$$352 \quad \begin{cases} \frac{\partial Q}{\partial x} + \frac{\partial A}{\partial t} = q \\ S_f = S_0 - \frac{\partial h}{\partial x} \end{cases} \quad (10)$$

353 A finite-difference method and the Newton–Raphson method were used for the iterative
 354 calculation of the above equation:

$$\begin{cases}
\left[Q_{i+1}^{t+1} \right]^{k+1} = \left[Q_{i+1}^{t+1} \right]^k - \frac{\frac{\Delta t}{\Delta x} \left[Q_{i+1}^{t+1} \right]^k + c \left(\left[Q_{i+1}^{t+1} \right]^k \right)^b - \frac{\Delta t}{\Delta x} Q_i^{t+1} - c \left(Q_{i+1}^t \right)^b - q_{i+1}^{t+1} \Delta t}{\frac{\Delta t}{\Delta x} + cb \left(\left[Q_{i+1}^{t+1} \right]^k \right)^{b-1}} \\
c = \left(\frac{1}{3600} n \chi^{\frac{2}{3}} S_f^{\frac{1}{2}} \right)^{\frac{3}{5}}
\end{cases} \quad (11)$$

356 where Q [L/s] is the water flow in surface river channel units, A [dm²] is the discharge
357 section area, c is a custom intermediate variable and χ [dm] is the wetted perimeter of the
358 discharge section area.

359 The underground runoff in the model includes the confluence of the epikarst zone and
360 underground river. In the epikarst zone, the karst water-bearing media are highly
361 heterogeneous (Williams, 2008). For example, the ~~anisotropic~~ karst fissure
362 systems and conduit systems consist of ~~large~~ the corrosion fractures. When rainfall
363 infiltrates into the epikarst zone, water moves slowly through the small (less than 10cm in
364 this study) karst fissure systems, while it flows rapidly in larger (more than 10cm) conduits.
365 The key to determining the confluence velocity lies in the width of karst fractures. In the
366 KHRUs (Fig. 3), the 10-cm width of the fracture was used as a threshold value (Atkinson,
367 1977) based on the borehole pumping test in the basin, meaning that if the fracture width
368 exceeded 10 cm, then the water movement into it was defined as rapid flow; otherwise, it
369 was defined as slow flow. The confluence in the epikarst zone was calculated by the
370 following equation (modified from Beven and Binley, 2006):

$$Q(t)_{ijk} = b_{ijk} \cdot \frac{\Delta h}{\Delta l} R_i C_j \cdot T(t)_{\text{slow/rapid}} \quad (12)$$

372 where

$$\begin{cases}
T(t)_{\text{slow}} = nr \frac{\rho g R_i C_j L_k}{12\nu} \\
T(t)_{\text{rapid}} = \frac{K_{ij} \left(e^{-f_{ij} h_{ij}} - e^{-f_{ij} z_{ij}} \right)}{f_{ij}}
\end{cases} \quad (13)$$

374 Here, $Q(t)_{ijk}$ [L/s] is the flow confluence in the epikarst zone at time t , b_{ijk} [dm] is the
375 runoff width, $\frac{\Delta h}{\Delta l}$ is the dimensionless hydraulic gradient, $T(t)_{\text{slow/rapid}}$ is the
376 dimensionless hydraulic conductivity, ρ [g/L] is the density of the water flow, g [m/s²] is
377 gravitational acceleration, n is the valid computational units, $R_i C_j L_k$ [L] is the volume of
378 the ijk -th KHRU, ν is the kinematic viscosity coefficient, f_{ij} is the attenuation coefficient in
379 the epikarst zone, h_{ij} [dm] is the depth of shallow groundwater and z_{ij} [dm] is the thickness
380 of the epikarst zone.

381 The distinction between rapid and slow flows in the epikarst zone is not absolute. The
382 10-cm width of a karst fracture as the dividing threshold is underrepresented due to the only
383 five limited boreholes have been tested for pumping in the region.also has some subjectivity.
384 In fact, there is usually water exchange between the rapid and slow flows at the junction of
385 large and small fissures in karst aquifers. In the QMG model, this water exchange can be
386 described with this equation (modified form Li et al., 2021):

$$387 \quad \begin{cases} Q = \alpha_{i,j,k} (h_n - h_{i,j,k}) \\ \alpha_{i,j,k} = \sum_{ip=1}^{np} \frac{(K_w)_{i,j,k} \pi d_{ip} \frac{1}{2} (\Delta l_{ip} \tau_{ip})}{r_{ip}} \end{cases} \quad (14)$$

388 Here, $\alpha_{i,j,k}$ [dm²/s] is the water exchange coefficient in the ijk -th KHRU, $(h_n - h_{i,j,k})$
389 [dm] is the water head difference between the rapid and slow flows at the junction of large
390 and small fissures in KHRUs, np is the number of fissure systems connected to the adjacent
391 conduit systems, $(K_w)_{i,j,k}$ [dm/s] is the permeability coefficient at the junction of a fissure
392 and conduit, d_{ip} and r_{ip} [dm] are the conduit diameter and radius, respectively, Δl_{ip}
393 [dm] is the length of the connection between conduits i and p , and τ_{ip} is the conduit
394 curvature. Some of the parameters in this equation, such as $(K_w)_{i,j,k}$ and $(h_n - h_{i,j,k})$,
395 were obtained by conducting an infiltration test in the study area.

396 The confluence of the underground river system plays an important role for the

397 confluence at the basin outlet. To facilitate the calculation of confluence in the QMG model,
 398 the underground river systems can be generalized into large multiple conduit systems.
 399 During floods, these conduit systems are mostly under pressure. Whether the water flow is
 400 laminar or turbulent depends on the flow regime at that time. The water flow into these
 401 conduits is calculated by the Hagen–Poiseuille equation and the Darcy–Weisbach equation
 402 (Shoemaker et al., 2008):

$$\begin{cases}
 Q_{\text{laminar}} = -A \frac{gd^2 \partial h}{32\nu \partial x} = -A \frac{\rho g d^2 \Delta h}{32\mu \tau \Delta l} \\
 Q_{\text{turbulent}} = -2A \sqrt{\frac{2gd|\Delta h|}{\Delta l \tau}} \log \left(\frac{H_c}{3.71d} + \frac{2.51\nu}{d \sqrt{\frac{2gd^3|\Delta h|}{\Delta l \tau}}} \right) \frac{\Delta h}{|\Delta h|}
 \end{cases} \quad (15)$$

404 Here, Q_{laminar} [L/s] is the water flow of the laminar flow in the conduit systems, A [dm²] is
 405 the conduit cross-sectional area, d [dm] is the conduit diameter, ρ [kg/dm³] is the density
 406 of the underground river, $\nu = \mu / \rho$ is the coefficient of kinematic viscosity, $\Delta h / \tau \Delta l$ is
 407 the hydraulic slope of the conduits, τ is the dimensionless conduit curvature, $Q_{\text{turbulent}}$ [L/s]
 408 is the turbulent flow in the conduit systems and H_c [dm] is the average conduit wall height.

409 3.2 Parameter optimization

410 In total, the QMG model has 12 parameters, of which flow direction and slope are
 411 topographic parameters that can be determined from the DEM without parametric
 412 optimization, while the remaining 10 parameters require calibration. Other distributed
 413 hydrological models with multiple structures usually have many parameters. For example,
 414 the Karst–Liuxihe model (Li et al., 2021) has 15 parameters that must be calibrated. In the
 415 QMG model, each parameter is normalized as

$$416 \quad x_i = x_i^* / x_{i0}, \quad (16)$$

417 where x_i is the dimensionless parameter value i after it is normalized, x_i^* is the parameter
 418 value i in actual physical units, and x_{i0} is the initial or final value of x_i . Through the

419 processing of Eq. (16), the value range of the model parameters is limited to a hypercube
 420 $K_n = (X \mid 0 \leq x_i \leq 1, i = 1, 2, \dots, n)$, K is a dimensionless value. This normalized treatment
 421 ignores the influence of the spatiotemporal variation of the underlying surface attributes on
 422 the parameters, while also simplifying the classification and number of the model parameters
 423 to a certain extent. Accordingly, the model parameters can be divided further into
 424 rainfall-evaporation ones, epikarst-zone ones and underground-river ones. Table 1 lists the
 425 parameters of the QMG model.

426 **Table 1.** Parameters of QMG model.

427 Because the QMG model has relatively few parameters, it is possible to calibrate them
 428 manually, which has the advantage that the operation is easy to implement and does not
 429 require a special program for parameter optimization. However, the disadvantage is that it is
 430 subjective, which can lead to great uncertainty in the manual parameter calibration process.
 431 To compare the effects of parameter optimization on model performance, this study used
 432 both manual parameter calibration and the improved chaotic particle swarm optimization
 433 algorithm (IPSO) for the automatic calibration of model parameters, and compared the
 434 effects of both on flood simulation.

435 In general, the structure and parameters of a standard particle swarm optimization
 436 algorithm (PSO) are simple, with the initial parameter values obtained at random. For
 437 parameter optimization in high-dimensional multi-peak hydrological models, the standard
 438 PSO is easily limited to a local convergence and cannot achieve the optimal effect, while the
 439 late evolution of the algorithm may also cause problems, such as precocity and stagnant
 440 evolution, due to the ‘inert’ aggregation of particles, which seriously affects the efficiency of
 441 parameter selection. It is necessary to overcome the above problems and make the algorithm
 442 converge to the global optimal solution with a high probability. In parameter optimization
 443 for the QMG model, we improved the standard PSO algorithm by adding chaos theory, and
 444 developed the IPSO, where 10 cycles of chaotic disturbances were added to improve the
 445 activity of the particles. The inverse mapping equation of the chaotic variable is

$$446 \begin{cases} X_{ij} = X_{\min} + (X_{\max} - X_{\min}) * Z_{ij} \\ Z'_{ij} = (1 - \alpha)Z^* + \alpha Z_{ij} \end{cases} \quad (17)$$

447 where X_{ij} is the optimization variable for the model parameters, $(X_{\max} - X_{\min})$ is the
448 difference between its maximum and its minimum, Z_{ij} is the variable before the disturbance is
449 added and Z'_{ij} represents the chaotic variables after a disturbance is added, α is a variable
450 determined by the adaptive algorithm, $0 \leq \alpha \leq 1$, and Z^* is the chaotic variable formed when
451 the optimal particle maps to the interval [0,1]. In parameter optimization, the flowchart of the
452 IPSO is shown in [Figure- 4](#).

453 **Figure 4.** Algorithm flow chart of IPSO.

454 3.3 Uncertainty analysis

455 Uncertainties in hydrological model simulation results usually originate from three aspects:
456 input data, model structure and model parameters (Krzysztofowicz, 2014). In the present
457 study, the input data (e.g. rainfall, flood events and some hydrogeological data) were first
458 validated and pre-processed through observations to reduce their uncertainties.

459 Second, we simplified the structure of the QMG model to reduce the structural
460 uncertainty. As a mathematical and physical model, a hydrological model has some
461 uncertainty in flood simulation and forecasting because of the errors in system structure and
462 the algorithm (Krzysztofowicz and Kelly, 2000). The model was designed with full
463 consideration of the relationship between the amount of data required to build the model and
464 its performance for flood simulation and forecasting in karst regions, and the model's entire
465 framework was integrated through simple structures and easy-to-implement algorithms,
466 using the concept of distributed hydrological modelling. Conventionally, the extent of
467 uncertainty is increased with the growing complexity of the model structure. We therefore
468 ensured that the structure of the QMG model was simple when it was designed, and the
469 model was divided into surface and underground double-layer structures to reduce its
470 structural uncertainty.

471 Third, we focus on analysing the uncertainty and sensitivity of the model parameters
472 and their optimization method, for which a multi-parametric sensitivity analysis method

473 (Choi et al., 1999; Li et al., 2020) was used to analyse the sensitivity of the parameters in the
474 QMG model. The steps in the parameter sensitivity analysis are as follows.

475 1) Selection of appropriate objective function

476 The Nash–Sutcliffe coefficient is widely used as the objective function to evaluate the
477 performance of hydrological models (Li et al., 2020, 2021). It was therefore used to assess
478 the QMG model. Because the most important factor in flood forecasting is the peak
479 discharge, it is used in the Nash coefficient equation:

$$480 \quad NSC = 1 - \frac{\sum_{i=1}^n (Q_i - Q_i')^2}{\sum_{i=1}^n (Q_i - \bar{Q})^2}, \quad (18)$$

481 where NSC is the Nash–Sutcliffe coefficient, Q_i [L/s] are the observed flow discharges, Q_i'
482 [L/s] are the simulated discharges, \bar{Q} [L/s] is the average observed discharge and n [h] is
483 the observation period.

484 2) Parameter sequence sampling

485 The Monte Carlo sampling method was used to sample 8000 groups of parameter
486 sequences. The parametric sensitivity of the QMG model was analysed and evaluated by
487 comparing the differences between the a priori and a posteriori distributions of the
488 parameters.

489 3) Parameter sensitivity assessment

490 The a priori distribution of a model parameter means its probability distribution, while
491 the a posteriori distribution refers to the conditional distribution calculated after sample
492 sampling, and it can be calculated based on the simulation result of the parametric
493 optimization. If there is a significant difference between the priori distribution and its
494 posteriori distribution~~them~~of the parameter, then the parameter being tested has a high
495 sensitivity, whereas if there is no obvious difference, then the parameter is insensitive. The
496 parametric priori distribution is calculated as

497

$$\begin{cases} P_{i,j}(NSC_{i,j} \geq 0.85) = \frac{n}{N+1} \times 100 \\ \sigma_i = \sum_{j=1}^n (P_{i,j} - \overline{P_{i,j}})^2 \end{cases} \quad (19)$$

498 where $P_{i,j}$ is the a priori distribution's probability when $NSC_{i,j} \geq 0.85$. We used a
 499 simulated Nash coefficient of 0.85 as the threshold value, and n was the number of
 500 occurrences of a Nash coefficient greater than 0.85 in flood simulations. In each simulation,
 501 only a certain parameter was changed, while the remaining parameters remained unchanged.
 502 If the Nash coefficient of this simulation exceeded 0.85, then the flood simulation results
 503 were considered acceptable. The term σ_i is the difference between the acceptable value
 504 and its mean, which represents the parametric sensitivity ($0 < \sigma_i < 1$). The higher the σ_i
 505 value, the more sensitive the parameter. N is the 8000 parameter sequences, and $\overline{P_{i,j}}$ is the
 506 average value of the a priori distribution.

507 3.4 Model Setting

508 Once the model was built, some of the initial conditions had to be set before running it
 509 to simulate and forecast floods, such as basin division, the setting of initial soil moisture, and
 510 the assumption of the initial parameter range. 1) In the study area, the entire Qingmuguan
 511 karst basin was divided into 893 KHRUs, including 65 surface river units, 466 hill slope
 512 units, and 362 underground river units. The division of these units formed the basis for
 513 calculating the process of runoff generation and convergence. 2) The initial soil moisture
 514 was set to 0–100% of the saturation moisture content in the basin, and the specific soil
 515 moisture before each flood had to be determined by a trial calculation. 3) The waterhead
 516 boundary conditions of the groundwater were determined by a tracer test in the basin, where
 517 a perennial stable water level adjacent the groundwater-divide was used as the fixed
 518 waterhead boundary. The base flow of the underground river was determined to be 35 L/s
 519 from the perennial average dry season runoff. 4) The range of initial parameters and
 520 convergence conditions were assumed before parameter optimization (Figure 4). 5)
 521 Parameter optimization and flood simulation validated the performance of the QMG model

522 in karst basins.

523 **4 Results and discussion**

524 **4.1 Parameter Sensitivity Results**

525 The number of parameters in a distributed hydrological model is generally large, and it
526 is important to perform a sensitivity analysis of each parameter to quantitatively assess the
527 impact of the different parameters on model performance. In the QMG model, each
528 parameter was divided into four categories according to its sensitivity: (i) highly sensitive,
529 (ii) sensitive, (iii) moderately sensitive, and (v) insensitive. In the calibration of model
530 parameters, insensitive ones do not need to be calibrated, which can greatly reduce the
531 amount of calculation and improve the efficiency of model operation.

532 The flow process in the calibration period (14 April to 10 May 2017) was adopted to
533 calculate the sensitivity of the model parameters, for which the calculation principle was
534 equation (19), and the parameter sensitivity results are calculated in Table 2.

535 Table 2 Parametric sensitivity results in QMG model.

536 In Table 2, the value of σ_i [equation (19)] represents a parameter's sensitivity, and the
537 higher the value, the more sensitive the parameter is. From the results in Table 2, it was
538 found that the rainfall infiltration coefficient, rock permeability coefficient, rock porosity,
539 and the related parameters of soil water content, such as the saturated water content, and
540 field capacity, were sensitive parameters. The order of parameter sensitivity was as follows:
541 infiltration coefficient > permeability coefficient > rock porosity > specific yield > saturated
542 water content > field capacity > flow direction > thickness > slope > Soil coefficient >
543 channel roughness > evaporation coefficient.

544 In the QMG model, parameters are classified as highly sensitive, sensitive, moderately
545 sensitive, and insensitive according to their influence on the flood simulation results. In
546 Table 4, we divided the sensitivity of model parameters into four levels based on the σ_i
547 value: 1) highly sensitive parameters, $0.8 < \sigma_i < 1$; 2) sensitive parameters, $0.65 < \sigma_i < 0.8$;

548 3) moderately sensitive parameters, $0.45 < \sigma_i < 0.65$; and 4) insensitive parameters,
549 $0 < \sigma_i < 0.45$. The highly sensitive parameters were the infiltration coefficient, permeability
550 coefficient, rock porosity, and specific yield. The sensitive parameters were the saturated
551 water content, field capacity, and thickness of the epikarst zone. The moderately sensitive
552 parameters were flow direction, slope, and soil coefficient. The insensitive parameters were
553 channel roughness and the evaporation coefficient.

554 **4.2 Parametric Optimization**

555 In total, the QMG model has 12 parameters, of which only eight need to be optimized,
556 which is relatively few for distributed models. The parameters of flow direction and slope as
557 well as the insensitive parameters of channel roughness and the evaporation coefficient need
558 not be calibrated, which can improve the convergence efficiency of the model parameter
559 optimization.

560 In the study area, 18 karst floods during the period ~~of~~ 14 April 2017 to 10 June 2019
561 were recorded at the underground river outlet to validate the effects of the QMG model in
562 karst hydrological simulations. The calibration period was 14 April to 10 May 2017 at the
563 beginning of the flow process, with the remainder of the time being the validation period. In
564 the QMG model, the IPSO algorithm was used to optimize the model parameters. To show
565 the necessity of parameter optimization for the distributed hydrological model, the study
566 specifically compared the flood simulations obtained using the initial parameters of the
567 model (without parameter calibration) and the optimized parameters. Figure- 5 shows the
568 iteration process of parameter optimization for the QMG model.

569 Figure 5 Iteration process of parametric optimization.

570 Figure- 5 shows that almost all parameters fluctuated widely at the beginning of the
571 optimization, and then after about 15 iterations of the optimization calculation, most of the
572 linear fluctuations become significantly less volatile, which indicated that the algorithm
573 tended to converge (possibly only locally). When the number of iterations exceeded 25, all
574 parameters remained essentially unchanged, meaning that the algorithm had converged (at
575 this point there was global convergence). It took only 25 iterations to reach a definite

576 convergence of the parameter rates with this IPSO algorithm, which is extremely efficient in
577 terms of the parameter optimization of distributed hydrological models. In previous studies
578 of the parametric optimization for the Karst-Liuxihe model in similar basin areas, 50
579 automatic parameter optimization iterations were required to reach convergence (Li et al.,
580 2021), demonstrating the effectiveness of the IPSO algorithm.

581 To evaluate the effect of parameter optimization, the convergence efficiency of the
582 algorithm, and more importantly, the parameters after calibration were used to simulate
583 floods. [Figure- 6](#) shows the flood simulation effects.

584 Figure 6 Flow simulation results of QMG model based on parameter optimization.

585 [Figure- 6](#) shows that the flows simulated by parameter optimization were better than
586 those simulated by the initial model parameters. The simulated flow processes based on the
587 initial parameters were relatively small, with the simulated peak flows in particular being
588 smaller than the observed values, and there were large errors between the two values. In
589 contrast, the simulated flows produced by the QMG model after parameter optimization
590 were very similar to the observed values, which indicates that calibration of the model
591 parameters is necessary and that there was an improvement in parameter optimization
592 through the use of the IPSO algorithm in this study. In addition, it was found that the flow
593 simulation effect was better in the calibration periods than in the validation periods (Fig. 6).

594 To compare the results of the flow processes simulation with the initial model
595 parameters and the optimized parameters, six evaluation indices (Nash–Sutcliffe coefficient,
596 correlation coefficient, relative flow process error, flood peak error, water balance
597 coefficient, and peak time error) were applied in this study, and the results are presented in
598 Table 3.

599 Table 3 Flood simulation evaluation index through parametric optimization.

600 Table 3 shows that the evaluation indices of the flood simulations after parametric
601 optimization were better than those of the initial model parameters. The average values of
602 the initial parameters for these six indices 0.81, 0.74, 27%, 31%, 0.80, and 5 h, respectively.
603 For the optimized parameters, the average values were 0.90, 0.91, 16%, 14%, 0.94, and 3 h,

604 respectively. The flood simulation effects after parameter optimization clearly improved,
605 implying that parameter optimization for the QMG model is necessary, and the IPSO
606 algorithm for parameter optimization is an effective approach that can greatly improve the
607 convergence efficiency of parameter optimization, and also ensure that the model performs
608 well in flood simulations.

609 **4.3 Model Validation in Flood Simulations**

610 Following parameter optimization, we simulated the whole flow process (14 April 2017
611 to 10 June 2019) based on the optimized and initial parameters of the QMG model (Fig. 6),
612 which enabled a visual reflection of the model used in the simulation of a long series of flow
613 processes. To reflect the simulation effect of the model for different flood events, we divided
614 the whole flow process into 18 flood events, then used the initial parameters of the model
615 and the optimized parameters, respectively, to verify the model performance in flood
616 simulations. [Figure- 7](#) and Table 4 show the flood simulation effects and their evaluation
617 indices using both the initial and the optimized parameters.

618 Figure 7 Flood simulation effects based on initial and optimized parameters.

619 Table 4 Flood simulation indices for model validation.

620 [Figure- 7](#) shows that the flood simulation results using the initial parameters were
621 smaller than the observed values, and the model performance improved in flood simulations
622 after parameter optimization. The simulated flood processes were in good agreement with
623 observations, and were especially effective for simulating flood peak flows. From flood
624 simulation indices in Table 4, the average water balance coefficient based on the initial
625 parameters was 0.69, i.e., much less than 1, indicating that the simulated water in the model
626 was unbalanced. After parameter optimization, the average value was 0.92, indicating that
627 parameter optimization had a significant impact on the model water balance calculation.

628 Table 4 shows that the average values of the six indices (Nash–Sutcliffe coefficient,
629 correlation coefficient, relative flow process error, flood peak error, water balance
630 coefficient, and peak time error) for the initial parameters were 0.79, 0.74, 26%, 25%, 0.69,
631 and 5 h, respectively, while for the optimized parameters the average values were 0.92, 0.90,

632 10%, 11%, 0.92, and 2 h, respectively. All evaluation indices improved after parameter
633 optimization, with the average values of the Nash coefficient, correlation coefficient, and
634 water balance coefficient increasing by 0.13, 0.16, and 0.23, respectively. The average
635 values of the relative flow process error, flood peak error, and peak time error decreased by
636 15%, 14%, and 3 h, respectively. These reasonable flood simulation results confirmed that
637 parameter optimization by the IPSO algorithm was necessary and effective for the QMG
638 model.

639 Compared with the overall flow process simulation shown in Figure 6, each flood
640 process was better simulated by the QMG model (Fig. 7). This was because in the function
641 of the QMG model and its algorithm design, the main consideration was the calculation of
642 the flood process, but the correlation algorithm of the dry season runoff was not described
643 well enough. For example, equations (12)–(15) are the flood convergence algorithm. As a
644 result, the model is not good at simulating other flow processes, such as dry season runoff,
645 leading to a low accuracy in the overall flow process. The next phase of our research will
646 focus on refining the algorithm related to dry season runoff and improving the
647 comprehensive performance of the model.

648 **4.4 Uncertainty analysis**

649 **4.4.1 Assessment and reduction of uncertainty**

650 In general, the uncertainty in model simulation is due mainly to three aspects of the model:
651 (i) the uncertainty of its input data, (ii) the uncertainty of its structure and algorithm and (iii)
652 the uncertainty of its parameters. In the practical application of a hydrological model, these
653 three uncertainties are usually interwoven, which leads to the overall uncertainty of the final
654 simulation results (Krzysztofowicz, 2014). Therefore, the present study focused on the
655 uncertainties in the input data, the model structure and the parameters to reduce the overall
656 uncertainty of the simulation results.

657 First, the input data—mainly rainfall-runoff data and hydrogeological data—were
658 pre-processed, which substantially reduced their uncertainty. Second, we simplified the
659 structure of the QMG model, which is reflected in the fact that it has only two layers of

660 spatial structure in the horizontal and vertical directions. This relatively simple structure
661 reduced greatly the uncertainty due to the model structure. In contrast, the underground
662 structure of our previous Karst–Liuxihe model (Li et al., 2021) has five layers, which leads
663 to great uncertainty. Third, appropriate algorithms for runoff generation and confluence were
664 selected. Different models were designed for different purposes, which leads to great
665 differences in the algorithms used. In the QMG model, most of the rainfall-runoff algorithms
666 used have been validated by the research results of others, and some of them were improved
667 to suit karst flood simulation and forecasting by the QMG model. For example, the
668 algorithm for the generation of excess infiltration runoff [Eq. (2)] was an improvement of
669 the version used in the Liuxihe model (Chen, 2009, 2018; Li et al., 2020). Finally, the
670 algorithm for parameter optimization was improved. Considering the shortcomings of the
671 standard PSO algorithm that tends to converge locally, this study developed the IPSO for
672 parameter optimization by adding chaotic perturbation factors. The flood simulation results
673 after parameter optimization were much better than those of the initial model parameters
674 (Figs. 6 and 7 and Tables 2 and 3), which indicates that parameter optimization is necessary
675 for a distributed hydrological model and can reduce the uncertainty of the model parameters.

676 **4.4.2 Parameter sensitivity analysis**

677 The parameter-sensitivity results in Table 2 show that the rainfall-infiltration coefficient in
678 the QMG model was the most sensitive parameter. It was the key to determining the
679 generation of excess infiltration surface runoff and separating surface runoff from subsurface
680 runoff. If the rainfall infiltration coefficient was greater than the infiltration capacity, excess
681 infiltration surface runoff was generated on the exposed karst landforms; otherwise, all
682 rainfall would infiltrate to meet the water deficit in the vadose zone, and then continue to
683 seep down into the underground river system, eventually flowing out of the basin through
684 the underground river outlet. The confluence modes of surface runoff and underground
685 runoff were completely different, resulting in a large difference in the simulated flow results.
686 Therefore, the rainfall infiltration coefficient had the greatest impact on the final flood
687 simulation results.

688 Other highly sensitive parameters such as the rock permeability coefficient, rock

689 porosity and specific yield were used as the basis for dividing between slow flow in karst
690 fissures and rapid flow in conduits. The division of slow and rapid flows also had a great
691 impact on the discharge at the outlet of the basin. Slow flow plays an important role in water
692 storage in a karst aquifer and is very important for the replenishment of river base flow in
693 the dry season. Rapid flow in large conduit systems dominates the flood runoff and is the
694 main component of the flood water volume in the flood season.

695 Parameters related to the soil water content, including the saturated water content, field
696 capacity and thickness, were sensitive parameters and had a large influence on the flood
697 simulation results. This is because the soil moisture content prior to flooding affects how
698 flood flows rise and when peaks occur. If the soil is already very wet or even saturated
699 before the flooding, the flood will rise quickly to reach a peak, and the process line of the
700 flood peak flow will be sharp and thin. This type of flood process forms easily and can lead
701 to disaster-causing flood events. In contrast, if the soil in the basin is very dry before the
702 flooding, the rainfall will first meet the water shortage of the vadose zone, and after it is
703 replenished the rainfall will infiltrate into the underground river. The flood peak of the river
704 basin outlet is therefore delayed.

705 The moderately sensitive parameters were flow direction, slope and the soil coefficient.
706 They had a specific influence on the flood simulation results, but the influence was not as
707 great as that of the highly sensitive and sensitive parameters. The insensitive parameters
708 were channel roughness and the evaporation coefficient. The amount of water lost by
709 evapotranspiration is very small in the total flood water, and it was therefore the least
710 sensitive parameter in the QMG model.

711 **5 Conclusions**

712 This study proposed a new distributed physically based hydrological model, i.e. the QMG
713 model, to simulate floods accurately in karst trough and valley landforms. The main
714 conclusions of this paper are as follows.

715 This QMG model has a high application potential in karst hydrology simulations. Other
716 distributed hydrological models usually have multiple structures, resulting in the need for a

717 large amount of data to build models in karst areas (Kraller et al., 2014). The QMG model
718 has only a double-layer structure, with a clear physical meaning, and a small amount of
719 basic data is needed to build the model in karst areas, such as some necessary
720 hydrogeological data. For example, the distribution and flow direction of underground rivers
721 is required, which can be inferred from a tracer test, leading to a low modelling cost. There
722 were fewer parameters in the QMG model than in other distributed hydrological models,
723 with only 10 parameters that needed to be calibrated.

724 The flood simulation after parameter optimization was much better than the simulation
725 using the initial model parameters. After parameter optimization, the average values of the
726 Nash coefficient, correlation coefficient and water balance coefficient increased by 0.13,
727 0.16 and 0.23, respectively, while the average relative flow process error, flood peak error
728 and peak time error decreased by 15%, 14% and 3 h, respectively. Parameter optimization is
729 necessary for a distributed hydrological model, and the improvement of the IPSO algorithm
730 in this study was an effective way to achieve this.

731 In the QMG model, the rainfall infiltration coefficient I_c , rock permeability coefficient
732 K , rock porosity R_p and the parameters related to the soil water content were sensitive
733 parameters. The order of parameter sensitivity was infiltration coefficient > permeability
734 coefficient > rock porosity > specific yield > saturated water content > field capacity > flow
735 direction > thickness > slope > soil coefficient > channel roughness > evaporation
736 coefficient.

737 This QMG model is suitable for karst trough and valley landform like this study
738 areabasins, where the topography is conducive to the spread of flood water. Whether this
739 model is applicable to ~~other the~~ karst areas of other landforms in non trough valley regions
740 still needs to be verified in the future studies. In addition, the basin area is very small, where
741 the hydrological similarity between different small basin areas varies greatly (Kong and Rui,
742 2003). The size of the area to be modelled has a great influence on the choice of model
743 spatial resolution (Chen et al., 2017). Therefore, whether the QMG model is suitable for
744 flood forecasting in large karst basins needs to be determined.

745 **Model development.**

746 This QMG model presented in this study uses the Visual Basic language programming. The
747 general framework of the model and the algorithm consist of three parts: the modeling
748 approach, the algorithm of rainfall-runoff generation and confluence, and the parameter
749 optimization algorithm. As a free and open source hydrological modeling program (QMG
750 model-V1.0), we provide all modeling packages, including model code, installation package,
751 simulation data package and user manual, free of charge. It is important to note that the
752 model we provide are for scientific research purposes only and should not be used for any
753 commercial purposes. Creative Commons Attribution 4.0 International.

754 Model installation program can be downloaded from ZENODO, cite as JI LI. (2021, June
755 16). QMG model-V1.0. Zenodo. <http://doi.org/10.5281/zenodo.4964701>, and

757 downloaded from <http://doi.org/10.5281/zenodo.4964754>.

758 **Code availability.**

759 All code for the QMG model-V1.0 in this paper are available and free, the code can be
760 downloaded from ZENODO, Cite as JI LI. (2021, June 16). QMG model-V1.0 code
761 (Version v1.0). Zenodo. <http://doi.org/10.5281/zenodo.4964709> (registration required).

762 **Data availability.**

763 All data used in this paper are available, findable, accessible, interoperable, and reusable.
764 The simulation data and modelling data package can be downloaded from
765 <http://doi.org/10.5281/zenodo.4964727>. The DEM was downloaded from the Shuttle Radar
766 Topography Mission database at <http://srtm.csi.cgiar.org>. The land use-type data were
767 downloaded from <http://landcover.usgs.gov>, and the soil-type data were downloaded from
768 <http://www.isric.org>. These data were last accessed on 15 October 2020.

769 **Author contributions.** JIL was responsible for the calculations and writing of the whole
770 paper. DY helped conceive the structure of the model. ZF and JL provided significant
771 assistance in the English translation of the paper. MM provided flow data of the study area.

772 **Competing interests.**

773 The authors declare that they have no conflicts of interest.

998 **Tables**

999 Table 1 Parameters of the QMG model.

Parameters	Variable name	Physical property
Infiltration coefficient	I_c	Meteorology
Evaporation coefficient	λ	Vegetation cover
Soil thickness	h	Karst aquifer
Soil coefficient	S_b	Soil type
Saturated water content	S_c	Soil type
Rock porosity	R_p	Karst aquifer
Field capacity	F_c	Soil type
Permeability coefficient	K	Karst aquifer
Flow direction	F_d	Landform
Slope	S_o	Landform
Specific yield	S_y	Karst aquifer
Channel roughness	n	Landform

1000 Table 2 Parametric sensitivity results in QMG model.

I_c	λ	h	S_b	S_c	S_y	F_d	S_o	R_p	F_c	K	n
0.92	0.24	0.71	0.58	0.8	0.83	0.74	0.68	0.86	0.78	0.89	0.36

1001 Table 3 Flood simulation evaluation index through parametric optimization.

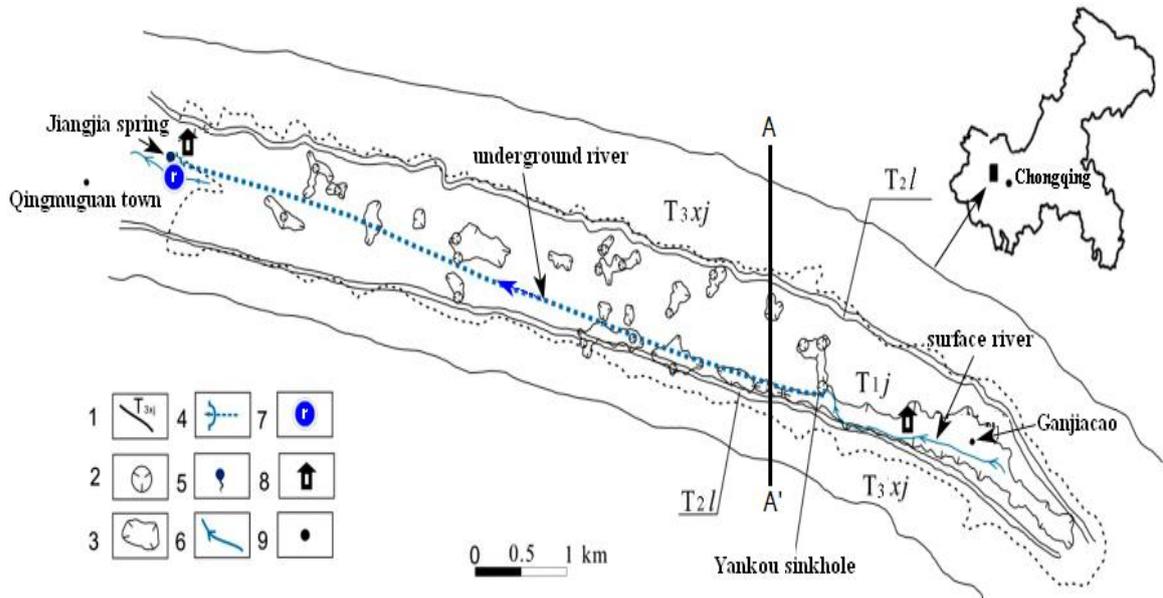

Parameter optimization	Parameter types	Nash coefficient	Correlation coefficient	Relative flow process error/%	Flood peak error/%	Water balance coefficient	Peak time error (hours)
calibration	initial	0.82	0.77	24	29	0.82	4
periods	optimized	0.91	0.94	14	12	0.95	2
validation	initial	0.79	0.71	29	32	0.77	6
