- 5 now at Fisheries and Oceans Canada, Mont Joli, Québec, Canada

19 **Abstract.** The ocean biogeochemistry components of [two new versions of](#) the Canadian Earth
20 System Model ~~v. 5~~ are presented and compared to observations and other models. CanESM5
21 employs the same [biogeochemistry module-ocean biology model](#) as CanESM2 whereas
22 CanESM5-CanOE (“Canadian Ocean Ecosystem model”) is a new, more complex
23 [biogeochemistry modulemodel](#) developed for CMIP6, with multiple food chains, flexible
24 phytoplankton elemental ratios, and a prognostic iron cycle. This new model is described in
25 detail and the outputs ([distributions of major tracers such as oxygen, dissolved inorganic carbon,](#)
26 [and alkalinity, the iron and nitrogen cycles, plankton biomass, and historical trends in CO₂](#)
27 [uptake and export production](#)) compared to CanESM5 and CanESM2, as well as to observations
28 and other CMIP6 models. Both CanESM5 models show gains in skill relative to CanESM2,
29 which are attributed primarily to improvements in ocean circulation. CanESM5-CanOE shows
30 improved skill relative to CanESM5 [in some areas for most major tracers at most depths](#).
31 CanESM5-CanOE includes a prognostic iron cycle, and maintains high nutrient / low
32 chlorophyll conditions in the expected regions (in CanESM2 and CanESM5, iron limitation is
33 specified as a temporally static ‘mask’). Surface nitrate concentrations are biased low in the
34 subarctic Pacific and equatorial Pacific, and high in the Southern Ocean, [in both CanESM5 and](#)
35 [CanESM5-CanOE](#). Export production in CanESM5-CanOE is among the lowest for CMIP6
36 models; in CanESM5 it is among the highest, but shows the most rapid decline after about 1980.
37 CanESM5-CanOE [shows some ability to simulate aspects of plankton community structure that a](#)
38 [single-species model can not \(e.g., seasonal dominance of large cells\), but is biased towards has](#)
39 [relatively](#) low concentrations of zooplankton and detritus relative to phytoplankton, ~~and a high~~
40 ~~and relatively constant living phytoplankton fraction of total particulate organic matter. In most~~
41 ~~regions, large and small phytoplankton show decoupled seasonal cycles with greater abundance~~

42 ~~of large phytoplankton in the productive seasons.~~ Cumulative ocean uptake of anthropogenic
43 carbon dioxide through 2014 is lower in both CanESM5 models than in observation-based
44 estimates ([145 PgC](#)) or the model ensemble mean ([144 PgC](#)), and is lower in CanESM5-CanOE
45 (122 PgC) than in CanESM5 (132 PgC).

46

47 1. Introduction

48

49 The Canadian Centre for Climate Modelling and Analysis has been developing coupled models
50 with an interactive carbon cycle for more than a decade (Arora et al., 2009; 2011; Christian et al.,
51 2010). [The Canadian Earth System Model version 5 \(CanESM5\)](#) (Swart et al., 2019a) is an
52 updated version of CanESM2 (Arora et al., 2011), with an ~~entirely~~ new ocean [model](#) and an
53 ~~atmosphere with the same T63 horizontal resolution and important improvements in atmospheric~~
54 ~~physics. The CanESM5 ocean is~~ based on the Nucleus for European Modelling of the Ocean
55 (NEMO) system version 3.4. The ocean biogeochemistry modules were developed in-house,
56 ~~although parameterizations for some processes were adapted from the native PISCES~~
57 ~~biogeochemistry model (Aumont et al., 2015)~~. CanESM5 uses the same [ocean biogeochemistry](#)
58 [biology](#) model as CanESM1 ([Christian et al., 2010](#)) and CanESM2 ([Arora et al., 2011](#)), the
59 Canadian Model of Ocean Carbon (CMOC; Zahariev et al., 2008), ~~adapted for use within~~
60 ~~NEMO~~. An additional model was developed for CMIP6, called the Canadian Ocean Ecosystem
61 model (CanOE). The biological components of CanOE are of substantially greater complexity
62 ~~than CMOC~~, including multiple food chains, flexible phytoplankton elemental ratios, and a
63 prognostic iron (Fe) cycle. ~~Carbon chemistry, gas exchange and solubility of carbon dioxide~~
64 ~~(CO₂) and oxygen are identical between the two and follow the protocols specified by the Ocean~~
65 ~~Model Intercomparison Project—Biogeochemistry (OMIP-BGC) (Orr et al., 2017)~~. The two
66 coupled models are known as CanESM5 and CanESM5-CanOE, respectively. ~~There are no~~
67 ~~feedbacks between biology and the physical ocean model, so the physical climate of CanESM5~~
68 ~~and CanESM5-CanOE is identical in experiments with prescribed atmospheric CO₂~~
69 ~~concentration.~~

70

71 The reasons for developing both models are, firstly, to evaluate the effect of changes in ocean
72 circulation between CanESM2 and CanESM5 on ocean biogeochemistry by running the new
73 climate model with the same ocean biogeochemistry, and secondly because CanOE is
74 substantially more expensive computationally ([as it has](#) 19 tracers vs 7 [the total computation cost](#)
75 [is 2-3 times greater](#)). ~~Having CMOC as an option allowed us to run many~~ Most CMIP6
76 experiments [were run](#) with CanESM5 only, as ocean biogeochemistry is not central to their
77 purpose. ~~Many a~~ Additional tracers requested by [the Ocean Model Intercomparison Project -](#)
78 [Biogeochemistry \(OMIP-BGC\)](#) including abiotic and natural dissolved inorganic carbon (DIC),
79 $DI^{14}C$, CFCs and SF_6 (see Orr et al., 2017) were run only in CanESM5, ~~since adding these~~
80 ~~tracers on top of the larger set of biological components in CanOE would have been~~
81 ~~prohibitively expensive~~. The CMIP6 experiments published for CanESM5-CanOE are listed in
82 Supplementary Table S1.

83

84 CMOC is a nutrient-phytoplankton-zooplankton-detritus (NPZD) model with highly
85 parameterized representations of phytoplankton Fe limitation, dinitrogen (N_2) fixation and
86 denitrification, and calcification and calcite dissolution (Zahariev et al., 2008; [Supplementary](#)
87 [Figure S1](#)). ~~In~~ CanESM1 and CanESM2, ~~CMOC~~ did not include oxygen; ~~In~~ CanESM5, ~~CMOC~~
88 ~~now~~ includes oxygen as a purely 'downstream' tracer that does not affect other biogeochemical
89 processes, ~~whereas in~~ [CanESM5-CanOE](#), denitrification is prognostic and dependent on the
90 concentration of oxygen. Among the less satisfactory aspects of CMOC biogeochemistry are,
91 firstly, that Fe limitation is specified as a static 'mask' that does not change with climate ([being it](#)
92 [is](#) calculated from the present-day climatological distribution of nitrate, [based on the assumption](#)

93 [that regions without iron limitation will have complete drawdown of surface nitrate at some point](#)
94 [in the year](#)), and secondly, that denitrification is parameterized so that nitrogen (N) is conserved
95 within each vertical column, i.e., collocated with N₂ fixation in tropical and subtropical open-
96 ocean regions (Zahariev et al., 2008; Riche and Christian, 2018). This latter simplification
97 produced excessive accumulations of nitrate in Eastern Boundary Current ([EBC](#)) regions where
98 most denitrification ~~actually~~ occurs. CMOC also has a tendency to produce rather stark extremes
99 of high and low primary and export production (Zahariev et al., 2008), a well-known problem of
100 NPZD models (Armstrong, 1994; Friedrichs et al., 2007). Our intent in developing CanOE was
101 to alleviate, or at least reduce, these biases, by including multiple food chains, a prognostic Fe
102 cycle, and prognostic denitrification. Dinitrogen fixation is still parameterized, but the CanOE
103 parameterization includes Fe ([but not P](#)) limitation, whereas in CMOC N₂ fixation tends to grow
104 without bound in a warming ocean as there is no P or Fe limitation (Riche and Christian, 2018).
105 ~~Calcification is represented by a prognostic detrital calcite pool with its own sinking rate (distinct~~
106 ~~from that of organic detritus), and calcite burial depends on the saturation state. In CMOC~~
107 ~~calcification is parameterized by a temperature dependent “rain ratio” and 100% burial of calcite~~
108 ~~that reaches the seafloor is assumed.~~

109

110 In this paper we present a detailed model description for CanOE and an evaluation of both
111 CanESM5 and CanESM5-CanOE relative to observational data products and other available
112 models. CMOC has been well described previously (Zahariev et al., 2008) and the details are not
113 reiterated here. In some cases, CanESM2 results are also shown to illustrate which differences in
114 the model solutions arise largely from the evolution of the physical ocean model, and which are
115 specifically associated with different representations of biogeochemistry. [An overall evaluation](#)

116 of the CanESM5 physical ocean model is given in Swart et al. (2019a). Here, we focus on
117 biogeochemical variables, and have evaluated model performance in three main areas: (1) the
118 distribution of major tracers like oxygen, DIC and alkalinity, and the resulting saturation state for
119 CaCO₃ minerals, (2) the iron cycle and its interaction with the nitrogen cycle, and (3) plankton
120 community structure and the concentration and export of particulates. We first address the major
121 chemical species that are common to both models (and almost all other Earth System Models) to
122 determine whether a more complex biology model measurably improves skill, and whether the
123 updated circulation model improves skill relative to CanESM2. Then we examine the areas
124 where our two models differ: the presence of a prognostic iron cycle and multiple food chains in
125 CanOE. More specifically, does CanESM5-CanOE reproduce the geographic distribution of
126 High-Nutrient, Low-Chlorophyll (HNLC) regions? Does the large phytoplankton / large
127 zooplankton food chain become dominant under nutrient-rich conditions, and how does having
128 multiple detrital size classes affect particle flux and remineralization length scale? Following this
129 model evaluation, we present historical trends in ocean anthropogenic CO₂ uptake, export
130 production, and total volume of low-oxygen waters over the historical (1850-2014) experiment.
131 Possible future changes under Shared Socioeconomic Pathway experiments will be addressed in
132 subsequent publications.

133

134 **2. Model Description**

135

136 CanESM5 (Swart et al., 2019a) is an updated version of CanESM2 (Arora et al., 2011), with an
137 entirely new ocean. The atmosphere model has the same T63 horizontal resolution, and contains
138 some important improvements in atmospheric physics (Swart et al., 2019a). The land surface

139 [\(Canadian Land Surface Scheme\) and terrestrial carbon cycle \(Canadian Terrestrial Ecosystem](#)
140 [Model\) models are substantially the same as in CanESM2 with minor modifications as described](#)
141 [by Arora et al. \(2020\). The CanESM5 ocean is based on the NEMO modelling system version](#)
142 [3.4, with a horizontal resolution of 1°, telescoping to 1/3° in the tropics, and 45 vertical levels](#)
143 [ranging in thickness from ~6 m near the surface to ~250 m in the deep ocean \(Swart et al.,](#)
144 [2019a\). All physical climate model components are the same in CanESM5 and CanESM5-](#)
145 [CanOE. There are no feedbacks between biology and the physical ocean model, so the physical](#)
146 [climate of CanESM5 and CanESM5-CanOE is identical in experiments with prescribed](#)
147 [atmospheric CO₂ concentration.](#)

148
149 The NEMO system is a publicly available archive of codes based on the OPA (Océan
150 PARallelisé) ocean model (Madec and Imbard, 1996; Guilyardi and Madec, 1997) [and the](#)
151 [Tracers in Ocean Paradigm \(TOP\) module for tracer advection and mixing. It comes with two](#)
152 [options for biogeochemistry: PISCES \(Pelagic Interactions Scheme for Carbon and Ecosystem](#)
153 [Studies\) and LOBSTER \(LODyC Ocean Biogeochemical System for Ecosystem and Resources\).](#)
154 [Our ocean biogeochemistry modules CanOE and the NEMO implementation of CMOC](#) are built
155 [around the basic code structure of PISCES](#) within [the Tracers in Ocean Paradigm \(TOP\) module,](#)
156 using NEMO v3.4.1, but have also been implemented in NEMO 3.6 for regional downscaling
157 applications (Holdsworth et al., 2021).

158
159 ~~The biology, carbon chemistry, gas exchange and light attenuation components have all been~~
160 ~~modified to various degrees. In a few cases PISCES parameterizations, or slightly modified~~
161 ~~versions thereof, were adopted. CanOE uses PISCES three band light attenuation while NEMO~~

162 ~~CMOC uses broadband attenuation of photosynthetically active radiation (PAR) for consistency~~
163 ~~with the published version of CMOC.~~ Carbon chemistry ~~was modified to be consistent with is~~
164 ~~based on~~ the Best Practices Guide (Dickson et al., 2007) and the OMIP-BGC data request (Orr et
165 al., 2017) ~~and are identical in CanESM5 and CanESM5-CanOE.~~ All calculations are done on the
166 total scale and the recommended formulae for the equilibrium constants are employed. ~~The~~
167 ~~PISCES conventions for convergence of e~~The carbon chemistry ~~solver~~ calculations were
168 ~~retained, the greater was run for a fixed~~ number of iterations (~~ten~~ in the surface layer, ~~and five in~~
169 ~~the subsurface layers in CanESM5-CanOE)~~ offering greater accuracy in calculating pCO₂ and gas
170 exchange. ~~In subsurface layers (where the only function of the carbon chemistry is to calculate~~
171 ~~burial of calcite in the sediments) the number of iterations is fixed at five.~~ CanESM5 uses the
172 ~~same carbon chemistry but~~ does not solve the carbon chemistry equations in the subsurface
173 layers. ~~OMIP-BGC formulations for CO₂ and O₂ solubility and gas exchange are employed. It is~~
174 ~~important to note here that the carbon chemistry and gas exchange formulations used in~~
175 ~~CanESM2 (and other CMIP5 models) are slightly different than those used in CMIP6. However,~~
176 ~~this difference is of little functional significance, i.e., it will have a negligible impact on the~~
177 ~~distribution of [CO₃²⁻] compared to the differences in DIC and alkalinity distribution. The~~
178 ~~initialization fields for nitrate, DIC and alkalinity were also different in CanESM2. This will~~
179 ~~affect the total ocean inventory of DIC but not the spatial distribution if the model is well~~
180 ~~equilibrated.~~

181

182 The CanOE biology model is a substantially new model based on the cellular regulation model
183 of Geider et al. (1998). There are two phytoplankton ~~functional group size classes~~, and each
184 group has four state variables: C, N, Fe and chlorophyll. Photosynthesis is decoupled from cell

185 production and photosynthetic rate is a function of the cell's internal N and Fe quotas. Each
 186 functional group has a specified minimum and maximum N quota and Fe quota, and nutrient
 187 uptake ceases when the maximal cell quota is reached. Chlorophyll synthesis is a function of N
 188 uptake and increases at low irradiance. [There are also two size classes each of zooplankton and](#)
 189 [detritus. Small zooplankton graze on small phytoplankton, while large zooplankton graze on both](#)
 190 [large phytoplankton and small zooplankton. Small detritus sinks at 2 m d⁻¹ and large detritus at](#)
 191 [30 m d⁻¹ \(in CanESM5 there is a single detrital pool with a sinking rate of 8 m d⁻¹\).](#) Model
 192 parameters and their values are listed in Table 1. A schematic of the model is shown in Figure 1.

193

194 **2.1 Photosynthesis and Phytoplankton Growth**

195

196 For simplicity and clarity, the equations are shown here for a single phytoplankton species, and
 197 do not differ structurally for small and large phytoplankton. Some parameter values differ for the
 198 two phytoplankton groups; all parameter values are listed in Table 1.

199

200 Temperature dependence of photosynthetic activity is expressed by the Arrhenius equation

$$201 \quad T_f = \exp\left(-\frac{E_{ap}}{R}\left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right) \quad (1)$$

202 where E_{ap} is an enzyme activation energy that corresponds approximately to that of RuBisCo (cf.
 203 Raven and Geider 1988), R is the gas constant (8.314 J mol⁻¹ K⁻¹), and temperature T and
 204 reference temperature T_{ref} are in Kelvin. Maximal rates of nutrient (either N or Fe, but
 205 generically referred to here with the superscript X) uptake are given by

$$206 \quad V_{max}^X = V_{ref}^X T_f \left(\frac{Q_{max}^X - Q^X}{Q_{max}^X - Q_{min}^X}\right)^{0.05} \quad (2)$$

207 where V_{max}^X is the maximal uptake rate in mg of nutrient X per mg of cell C, X can represent N
 208 or Fe, Q is the nutrient cell quota and Q_{min} and Q_{max} its minimum and maximum values, and V_{ref}^X
 209 is a (specified) basal rate at $T=T_{ref}$ and $Q=Q_{min}$. These maximum rates are then reduced according
 210 to the ambient nutrient concentration, i.e.

$$211 \quad V^N = V_{max}^N (L_{NH4} + (1 - L_{NH4})L_{NO3}) \quad (3a)$$

212 where $L_{NH4} = \frac{N_a}{K_{NaX} + N_a}$ and $L_{NO3} = \frac{N_i}{K_{NiX} + N_i}$, with N_i and N_a indicating nitrate and ammonium
 213 respectively, and

$$214 \quad V^{Fe} = V_{max}^{Fe} \left(\frac{Fe}{K_{FeX} + Fe} \right) \quad (3b)$$

215 where X indicates large or small phytoplankton (Table 1). The maximal carbon-based growth
 216 rate is given by

$$217 \quad P_{max}^C = P_{ref}^C T_f \min \left\{ \frac{Q^N - Q_{min}^N}{Q_{max}^N - Q_{min}^N} \cdot \frac{Q^{Fe} - Q_{min}^{Fe}}{Q_{max}^{Fe} - Q_{min}^{Fe}} \right\} \quad (4)$$

218 where P_{ref}^C is the rate at the reference temperature T_{ref} under nutrient-replete conditions
 219 ($Q=Q_{max}$). The light-limited growth rate is then given by

$$220 \quad P_{phot}^C = P_{max}^C \left(1 - e^{-\alpha_{chl} E \theta_C / P_{max}^C} \right) \quad (5)$$

221 where [E is irradiance and](#) θ_C is the chlorophyll-to-carbon ratio. The rate of chlorophyll synthesis
 222 is

$$223 \quad \rho_{chl} = \theta_{max}^N \frac{P_{phot}^C}{E \alpha_{chl} \theta} \quad (6)$$

224 These rates are then used to define a set of state equations for phytoplankton carbon (C_p),
 225 nitrogen (N_p), iron (Fe_p), and chlorophyll (M).

$$226 \quad \frac{dC_p}{dt} = (P_{phot}^C - \zeta V_N) C_p - (G + C_{XS}) - m_1 C_p - m_2 C_p^2 - k_{XU} C_{INTR} \quad (7)$$

227 where ζ is the respiratory cost of biosynthesis, G is the grazing rate (equation 12), C_{XS} is the
 228 excess (above the ratio in grazer biomass) carbon in grazing losses ([see below equation 16a](#)), m_1
 229 and m_2 are coefficients for linear and quadratic nonspecific mortality terms, C_{INTR} is the
 230 concentration of intracellular carbohydrate carbon in excess of biosynthetic requirements, and
 231 k_{XU} is a rate coefficient for its exudation to the environment. The nonspecific mortality terms are
 232 set to 0 below $0.01 \text{ mmol C m}^{-3}$, to prevent biomass from being driven to excessively low levels
 233 in the high latitudes in winter; [linear mortality terms can result in biomass declining to levels](#)
 234 [from which recovery would take much longer than the brief Arctic summer](#) (Hayashida, 2018).

235 The full equation for phytoplankton N, Fe and chlorophyll are

$$236 \quad \frac{dN_p}{dt} = \frac{V^N}{Q_N} - (G + m_1 C_p + m_2 C_p^2) R_{NC} - N_{XS} \quad (8)$$

$$237 \quad \frac{dFe_p}{dt} = \frac{V^{Fe}}{Q_{Fe}} - (G + m_1 C_p + m_2 C_p^2) R_{FeC} - Fe_{XS} \quad (9)$$

$$238 \quad \frac{dM}{dt} = \frac{\rho_{chl} V^N}{\theta_C} M - (G + m_1 C_p + m_2 C_p^2) \theta_C - k_{dgr} M \quad (10)$$

239 where k_{dgr} is a rate coefficient for nonspecific losses of chlorophyll e.g., by photooxidation, in
 240 addition to losses to grazing and other processes that also affect C_p , N_p , and Fe_p . N_{XS} and Fe_{XS} are
 241 remineralization of "excess" (relative to grazer or detritus ratios) N or Fe and are defined below
 242 (equation 16).

243

244 **2.2 Grazing and Food Web Interactions**

245

246 Grazing rate depends on the phytoplankton carbon concentration, which most closely represents
 247 the food concentration available to the grazer (Elser and Urabe 1999; Loladze et al. 2000).

248 Zooplankton biomass is also in carbon units. State equations for small and large zooplankton are

$$249 \quad \frac{dZ_s}{dt} = \lambda G_s - (R + G_Z + m_{1s}Z_s + m_{2s}Z_s^2) \quad (11a)$$

$$250 \quad \frac{dZ_L}{dt} = \lambda G_L - (R + m_{1L}Z_L + m_{2L}Z_L^2) \quad (11b)$$

251 where

$$252 \quad G_s = G_{s0}(1 - e^{-a_s C_{ps}})Z_s \quad (12a)$$

$$253 \quad G_L = G_{L0}(1 - e^{-a_l(C_{pl}+Z_s)})Z_L \quad (12b)$$

254 for small and large zooplankton respectively, G_Z is grazing of small zooplankton by large
 255 zooplankton, R is respiration, and m_1 and m_2 are nongrazing mortality rates. Large zooplankton
 256 grazing is divided into grazing on large phytoplankton and small zooplankton in proportion to
 257 the relative abundance of each

$$258 \quad G_P = G_L \frac{P_L}{P_L+Z_s} \quad (13a)$$

$$259 \quad G_Z = G_L \frac{Z_s}{P_L+Z_s} \quad (13b)$$

260 Zooplankton biomass loss to respiration is given by

$$261 \quad R = \max\{r_z T_f Z - C_{XS}, 0\} \quad (14)$$

262 and uses the same activation energy as photosynthesis. Respiration (R) is assumed to consume
 263 only carbon and not result in catabolism of existing biomass when “excess” carbon is available
 264 in the prey. In addition, conservation of mass must be maintained by recycling to the dissolved
 265 pool grazer consumption of elements in excess of biosynthetic requirements when grazer and
 266 prey elemental ratios differ. In the case where the nutrient quota (relative to carbon) exceeds the

267 grazer fixed ratio, the excess nutrient is remineralized to the dissolved inorganic pool. In the case
 268 where the nutrient quota is less than the grazer ratio, the grazer intake is reduced to what can be
 269 supported by the least abundant nutrient (relative to the grazer biomass ratio) and excess carbon
 270 is remineralized. For the case of two nutrients (in this case N and Fe) it is necessary to define

$$271 \quad G' = G \min \left\{ \frac{N_P}{C_P} R_{CN}, \frac{Fe_P}{C_P} R_{CFe}, 1 \right\} \quad (15)$$

272 where G is equal to G_S (equation 12a) for small zooplankton and G_P (equation 13a) for large
 273 zooplankton, and R_{XY} indicates the fixed ratio of element X to element Y in grazer biomass. The
 274 'excess' carbon available for respiration is

$$275 \quad C_{XS} = G' \left\{ \frac{C_P}{N_P} R_{NC} - 1, \frac{C_P}{Fe_P} R_{FeC} - 1, 0 \right\} \quad (16a)$$

276 and the excess nutrients remineralized to their inorganic pools are

$$277 \quad N_{XS} = G' \max \left\{ \frac{N_P}{C_P} - R_{NC}, 0 \right\} \varepsilon + G' \max \left\{ R_{NC} \left(\frac{N_P}{Fe_P} R_{FeN} - 1 \right), 0 \right\} (1 - \varepsilon) \quad (16b)$$

$$278 \quad Fe_{XS} = G' \max \left\{ \frac{Fe_P}{C_P} - R_{FeC}, 0 \right\} \varepsilon + G' \max \left\{ R_{FeC} \left(\frac{Fe_P}{N_P} R_{NFe} - 1 \right), 0 \right\} (1 - \varepsilon) \quad (16c)$$

279 where

$$280 \quad \varepsilon = \frac{\max\{C_{XS}, 0\}}{C_{XS} + \Delta}$$

281 is a switch to prevent double-counting in cases where one of the terms is redundant (the excess
 282 relative to the least abundant element is included in the other term), but would otherwise be
 283 nonzero (Δ is a constant equal to 10^{-15} , to prevent divide-by-zero). For three elements, there are
 284 $3! = 6$ possible cases: for N greater or less than $C_P R_{NC}$, Fe may be either in excess relative to
 285 both C and N, deficient relative to both, or in excess relative to one but not the other (Table 2).

286

287 2.3 Organic and Inorganic Pools

288

289 There are two pools of detritus with different sinking rates but the same fixed elemental ratios.

290 Detrital C/N/Fe ratios are the same as zooplankton, so zooplankton mortality or grazing of small

291 zooplankton by large zooplankton produce no 'excess'. Phytoplankton mortality, and defecation

292 by zooplankton grazing on phytoplankton, produces excess nutrient or excess C that needs to be

293 recycled into the inorganic pool in a similar fashion as outlined above for the assimilated fraction

294 of grazing on phytoplankton.

295 The conservation equations for detrital C are

$$296 \frac{dD_s}{dt} = m_1(C_{ps} + Z_s) + m_2(C_{ps}^2 + Z_s^2) - r_1 D_s T_g - w_s \frac{dD_s}{dz} \quad (17a)$$

$$297 \frac{dD_l}{dt} = m_1(C_{pl} + Z_l) + m_2(C_{pl}^2 + Z_l^2) - r_2 D_l T_g - w_l \frac{dD_l}{dz} \quad (17b)$$

298 where T_g is an Arrhenius function for temperature dependence of remineralization and w is the

299 sinking speed. The conservation equations for inorganic C, N, and Fe are

$$300 \frac{dC_i}{dt} = (\zeta V^N - P_{\text{phot}}^C) C_p + R + C_{\text{XS}} + (r_1 D_s + r_2 D_l) T_g \quad (18a)$$

$$301 \frac{dN_i}{dt} = -\frac{V^N}{Q^N} N_p \left(\frac{L_{\text{NO}_3}}{L_{\text{NO}_3} + L_{\text{NH}_4}} \right) + N_{\text{ox}} - N_{\text{dentr}} (1 - A_f) \quad (18b)$$

$$302 \frac{dN_a}{dt} = -\frac{V^N}{Q^N} N_p \left(\frac{L_{\text{NH}_4}}{L_{\text{NO}_3} + L_{\text{NH}_4}} \right) + \frac{R}{R_{\text{CN}}} + N_{\text{XS}} + (r_1 D_s + r_2 D_l) R_{\text{NC}} T_g - N_{\text{ox}} + N_{\text{dnf}} - N_{\text{dentr}} A_f \quad (18c)$$

$$303 \frac{d\text{Fe}}{dt} = \frac{V^{\text{Fe}}}{Q^{\text{Fe}}} \text{Fe}_p + \frac{R}{R_{\text{CFe}}} + \text{Fe}_{\text{XS}} + (r_1 D_s + r_2 D_l) R_{\text{FeC}} T_g \quad (18d)$$

304 where N_{ox} is microbial oxidation of ammonium to nitrate (nitrification), N_{dnf} and N_{dentr} are

305 sources and sinks associated with dinitrogen fixation and denitrification, and A_f is the ammonium

306 fraction of denitrification losses, associated with anaerobic ammonium oxidation ("anammox").

307 The oxygen equation is essentially the inverse of equation 18a, with additional terms for
 308 oxidation and reduction of N, i.e.,

$$309 \quad \frac{dO_2}{dt} = -\frac{dC_i}{dt} + 2\frac{V^N}{Q^N}N_p\left(\frac{L_{NO_3}}{L_{NO_3}+L_{NH_4}}\right) - 2N_{ox} \quad (19)$$

310 Nitrification is given by

$$311 \quad N_{ox} = k_{NH_4ox}N_a\frac{K_E}{K_E+E(z)} \quad (20)$$

312 where $E(z)$ is the layer mean irradiance at depth z . Dinitrogen fixation is parameterized as an
 313 external input of ammonium dependent on light, temperature and Fe availability, and inhibited
 314 by high ambient concentrations of inorganic N,

$$315 \quad N_{dnf} = k_{dnf}T_{dnf}(1 - e^{-aE})\left(\frac{Fe}{K_{Fe}+Fe}\right)\left(\frac{K_{NO_3}}{K_{NO_3}+N_i+N_a}\right) \quad (21)$$

316 where $T_{dnf} = \max(0, 1.962(T_f - 0.773))$, i.e., a linear multiple of equation (1) that is 0 at $T < 20^\circ\text{C}$
 317 and unity at $T = 30^\circ\text{C}$.

318

319 Denitrification is parameterized as a fraction of total remineralization that increases as a linear
 320 function of oxygen concentration for concentrations less than a threshold concentration O_{mxd}

$$321 \quad N_{frxn} = 1 - \frac{\min(O_2, O_{mxd})}{O_{mxd}} \quad (22)$$

322 Remineralization is then divided among oxygen ($1 - N_{frxn}$), nitrate ($0.875N_{frxn}$), and ammonium
 323 ($0.125N_{frxn}$) assuming an average anammox contribution of 25% (Babbin et al., 2014). We use
 324 this average ratio of anammox to classical denitrification to partition fixed N losses between
 325 NO_3^- and NH_4^+ ; the DIC sink and organic matter source associated with anammox are small and
 326 are neglected here.

327

328 2.4 Calcification, Calcite Dissolution, and Alkalinity

329

330 [In CanOE, calcification is represented by a prognostic detrital calcite pool with its own sinking](#)
331 [rate \(distinct from that of organic detritus\), and calcite burial or dissolution in the sediments](#)
332 [depends on the saturation state \(100% burial when \$\Omega_C \geq 1\$, 100% dissolution when \$\Omega_C < 1\$ \).](#)

333 Calcification is represented by a detrital calcium carbonate (CaCO_3) state variable, but no
334 explicit calcifier groups. Detrital CaCO_3 sinks in the same fashion as detrital particulate organic
335 carbon (POC), with a sinking rate independent of those for large and small organic detritus.

336 Calcite production is represented as a fixed fraction of detritus production from small
337 phytoplankton and small zooplankton mortality:

$$338 \frac{dCa}{dt} = m_1(C_{ps} + Z_s)P_{Ca} + m_2(C_{ps}^2 + Z_s^2)P_{Ca} - k_{Ca}Ca - w_{Ca} \frac{dCa}{dz} \quad (23)$$

339 Calcite dissolution occurs throughout the water column as a first order process (i.e., no
340 dependence on temperature or saturation state). Approximately 80% of calcite produced is
341 exported from the euphotic zone. Burial in the sediments is represented as a simple 'on/off'
342 switch dependent on the calcite saturation state (zero when $\Omega_C < 1$ and 1 when $\Omega_C \geq 1$). [In](#)
343 [CanESM5, calcification is parameterized by a temperature dependent “rain ratio” \(Zahariev et](#)
344 [al., 2008\) and 100% burial of calcite that reaches the seafloor is assumed.](#) Calcite burial [in both](#)
345 [models](#) is balanced by an equivalent source of DIC and alkalinity at the ocean surface [\(in the](#)
346 [same vertical column\)](#) as a crude parameterization of fluvial sources.

347

348 For each mole of calcite production two moles of alkalinity equivalent are lost from the
349 dissolved phase; the reverse occurs during calcite dissolution. There are additional sources and
350 sinks for alkalinity associated with phytoplankton nutrient (NH_4^+ , NO_3^-) uptake, organic matter

351 remineralization, nitrification, denitrification and dinitrogen fixation (Wolf-Gladrow et al., 2007,
352 see Supplementary Table S2). The anammox reaction does not in itself contribute to alkalinity
353 (Jetten et al., 2001), but there is a sink associated with ammonium oxidation to nitrite (the model
354 does not distinguish between nitrite and nitrate). Autotrophic production of organic matter by
355 anammox bacteria is a net source of alkalinity (Strous et al., 1998) but this source is extremely
356 small (~ 0.03 mol/molN) and is neglected here. Globally, the sources and sinks of alkalinity from
357 the N cycle offset each other such that there is no net gain or loss as long as the global fixed N
358 pool is conserved (see below Sect. 2.5). If dinitrogen fixation and denitrification are allowed to
359 vary freely, there will generally be a net gain or loss of fixed N and, therefore, of alkalinity.

360

361 **2.5 External Nutrient Sources and Sinks**

362

363 External sources and sinks consist of river inputs, aeolian deposition, biological N₂ fixation,
364 denitrification, mobilization of Fe from reducing sediments, loss of Fe to scavenging, and burial
365 of calcium carbonate in the sediments. Aeolian deposition of Fe is calculated from a climatology
366 of mineral dust deposition generated from offline (atmosphere-only) simulations with CanAM4
367 (von Salzen et al., 2013), with an Fe mass fraction of 5% and a fractional solubility of 1.4% in
368 the surface layer. Subsurface dissolution is parameterized based on PISCES v2 (Aumont et al.,
369 2015); the total dissolution is 6.35%, with 22% of soluble Fe input into the first vertical layer
370 (see Supplementary material). Iron from reducing sediments is also based on PISCES, with a
371 constant areal flux of $1000 \text{ nmol m}^{-2} \text{ d}^{-1}$ in the first model level, declining exponentially with
372 increasing seafloor depth (i.e., assuming that [shelf sediments are the strongest source and](#) the
373 sediments become progressively more oxygenated [with increasing seafloor depth](#)) with an e-

374 folding length scale of about 200 m. Scavenging of dissolved iron is first-order with a high rate
375 (2.5 d^{-1}) for concentrations in excess of 0.6 nM (Johnson et al., 1997). For concentrations below
376 this threshold, the rate is much lower (0.001 d^{-1}) and is weighted by the concentration of organic
377 detritus (Christian et al., 2002b), i.e.,

$$378 \quad \frac{dFe}{dt} = -FeS_{Fe1} \min\{(D_S + D_L)P_{Fe}, 1\} \quad (24)$$

379 where Fe is the dissolved iron concentration, D_S and D_L are the small and large detritus
380 concentrations, S_{Fe1} is the first-order scavenging rate in surface waters with abundant
381 particulates, and P_{Fe} is an empirical parameter to determine the dependence on particle
382 concentration (Table 1). The basis for this parameterization is that the rate of scavenging must
383 depend not only on the concentration of iron but on the concentration of particles available for it
384 to precipitate onto, and assumes that POC is strongly positively correlated with total particulate
385 matter. Scavenging is treated as irreversible, i.e., scavenged Fe is not tracked and does not
386 reenter the dissolved phase.

387
388 ~~Unlike in CMOC,~~ N_2 fixation and denitrification vary independently in CanOE, so the global
389 total N pool can change. Conservation is imposed by adjusting the global total N pool according
390 to the difference between the gain from N_2 fixation and the loss to denitrification. A slight
391 adjustment is applied to the nitrate concentration at every grid point, while preserving the overall
392 spatial structure of the nitrate field. Adjustments are multiplicative rather than additive to avoid
393 producing negative concentrations. This adjustment does not maintain (to machine precision) a
394 constant global N inventory but is intended to minimize long term drift, keeping it much smaller
395 than the free surface error (see below). This adjustment is applied every 10 days and has a
396 magnitude of approximately 7×10^{-8} of the total N.

397

398 [When the total fixed N adjustment is applied, ~~One one~~](#) mole of alkalinity is removed per mole of
399 N added or removed, [to account for the ~~since there are~~](#) alkalinity sources [of ~~1 mol/molN~~](#)
400 associated with [both](#) N₂ fixation (creation of new NH₄⁺) and denitrification (removal of NO₃⁻)
401 [\(Wolf-Gladrow et al., 2007, see Supplementary Table S2\). As there is, ~~offset by~~](#) a 2 mol/molN
402 sink associated with nitrification, [this formulation is globally conservative](#). As noted above, [in](#)
403 [CanOE](#) CaCO₃ can dissolve or be buried in the sediments depending on the calcite saturation
404 [state](#). DIC and alkalinity lost to burial are reintroduced at the ocean surface, at the same grid
405 point as burial occurs, providing a crude parameterization of river inputs so that global
406 conservation is maintained (fresh water runoff contains no DIC or alkalinity). However, the OPA
407 free surface formulation is inherently imperfect with regard to tracer conservation. Drift in total
408 ocean alkalinity and nitrogen over time is on the order of 0.01% and 0.03% per thousand years,
409 respectively (losses due to the free surface are generally larger for tracers with less homogeneous
410 distributions).

411

412 **2.6 Ancillary data**

413

414 For first-order model validation we have relied largely on global gridded data products rather
415 than individual profile data. Global gridded data from World Ocean Atlas [20132018](#)
416 (WOA[20132018](#)) (Locarnini et al., [20132018](#); Zweng et al., [20132018](#); Garcia et al.,
417 [2014a2018a](#); [2014b2018b](#)) were used for temperature, salinity, and oxygen and nitrate
418 concentration. DIC and alkalinity were taken from the GLODAP[v2.2016b](#) gridded data product
419 ([Key et al., 2015](#); Lauvset et al., 2016). Offline carbon chemistry calculations were done

420 following the Best Practices Guide (Dickson et al., 2007) and the OMIP-BGC protocols (Orr et
421 al., 2017), [which and](#) are identical to those used in the models except that constant reference
422 concentrations were used for phosphate (1 μM) and silicate (10 μM).

423
424 There is no global gridded data product for Fe, but we have made use of the GEOTRACES
425 Intermediate Data Product 2017 (Schlitzer et al., 2018), and the data compilations from MBARI
426 (Johnson et al., 1997; 2003) and PICES Working Group 22 (Takeda et al., 2013). The latter two
427 are concentrated in the Pacific, while GEOTRACES is more global. The combined data sets
428 provide more than 10000 bottle samples from more than 1000 different locations (Supplementary
429 [Figure S4aS9a](#)) (excluding some surface transect data that involve frequent sampling of closely
430 spaced locations along the ship track). More detail about model comparison to these data
431 compilations and the list of original references are given in the Supplementary information.

432
433 Satellite ocean colour estimates of surface chlorophyll were taken from the combined
434 SeaWiFS/MODIS climatology described by Tesdal et al. (2016). Climatological satellite POC
435 was downloaded from the NASA ocean colour web site and is based on the algorithm of
436 Stramski et al. (2008) using MODIS-Aqua data. This climatology differs slightly from the
437 chlorophyll one in terms of years included and sensors utilized, but as only climatological
438 concentrations are considered and each climatology covers ~ 15 years, these differences will have
439 negligible effect on the results presented. [Satellite chlorophyll concentrations greater than 1 mg](#)
440 [m⁻³ were excluded as these are mostly associated with coastal regions not resolved by coarse-](#)
441 [resolution global ocean models.](#)

442

443 CMIP6 model data were regridded [by distance-weighted averaging using the Climate Data](#)
444 [Operators \(https://code.mpimet.mpg.de/projects/cdo/\)](#) to a common grid (2x2°, 33 levels) to
445 [facilitate ensemble averaging. The vertical levels used are those used in GLODAP and in earlier](#)
446 [\(through 2009\) versions of the World Ocean Atlas \(e.g., Locarnini et al., 2010\). following the](#)
447 [GLODAP levels\) to facilitate ensemble averaging. For large scale tracer distributions, using a 1°](#)
448 [or 2° grid makes little difference \(for example, the spatial pattern correlation between CanESM5](#)
449 [and observed oxygen concentration at specific depths differs by an average of 0.0011\).](#) The years
450 1986-2005 of the Historical experiment were averaged into climatologies or annual means, for
451 meaningful comparison with observation-based data products. [The CMIP6 Historical experiment](#)
452 [runs from 1850-2014 with atmospheric CO₂ concentration \(and other atmospheric forcings\)](#)
453 [based on historical observed values.](#) A single realization was used in each case ([see Table S3](#)); as
454 20 year averages are used, internal variability is assumed to have little effect (e.g., Arguez and
455 Vose, 2011, [see Table S4](#)). [Where time series are shown, 5-year means are used.](#)

456
457 Sampling among CMIP6 models was somewhat opportunistic and the exact suite of models
458 varies among the analyses presented. When we conducted a search for a particular data field, we
459 included in the search parameters all models that published that field, and repeated the search at
460 least once for models that were unavailable the first time the search was executed. In some cases,
461 model ensemble means excluded all but one model from a particular ‘family’ (e.g., there are
462 three different MPI-ESM models for which ocean biogeochemistry fields were published), as the
463 solutions were found to be similar and would bias the ensemble mean towards their particular
464 climate. [The models used are ACCESS-ESM1-5, CESM2, CESM2-WACCM, CNRM-ESM2-1,](#)
465 [GFDL-CM4, GFDL-ESM4, IPSL-CM6A-LR, MIROC-ES2L, MPI-ESM-1-2-HAM, MPI-](#)

466 [ESM1-2-LR, MPI-ESM1-2-HR, MRI-ESM2-0, NorESM2-LM, NorESM2-MM, and UKESM1-](#)
467 [0-LL. More details of which variables and realizations are used for which models are given in](#)
468 Supplementary Table S3.

469

470 **3. Results**

471

472 [We first describe here the large-scale distribution of oxygen, DIC, alkalinity, and the saturation](#)
473 [state with respect to CaCO₃ that derives from these large-scale tracer distributions. Tracer](#)
474 [distributions result partly from ocean circulation and partly from biogeochemical processes. An](#)
475 [overall evaluation of the ocean circulation model is given in Swart et al. \(2019a\). Analyzing](#)
476 [CanESM5 and CanESM5-CanOE \(with identical circulation\) as well as CanESM2 where](#)
477 [possible \(same biogeochemistry as CanESM5 but different circulation\) allows us to separate the](#)
478 [effects of physical circulation and biogeochemistry on evolving model skill with respect to large-](#)
479 [scale tracer distributions. In subsequent sections we address the main areas where CanESM5 and](#)
480 [CanESM5-CanOE differ, such as the interaction of the iron and nitrogen cycles and plankton](#)
481 [community structure. Finally, we present some temporal trends over the course of the historical](#)
482 [experiment \(1850-2014\).](#)

483

484 **3.1 Distribution of oxygen**

485

486 The spatial distribution of oxygen concentration ($[O_2]$) at selected intermediate depths (400, 900,
487 and 1400 m) [is shown in Figure 2 for gridded data from WOA2018 and differences of](#)
488 CanESM5, CanESM5-CanOE, a model ensemble mean (MEM) of CMIP6 models (excluding

489 CanESM5 and CanESM5-CanOE) from the observational data product, and gridded data from
490 WOA2013 is shown in Figure 2. The depths were chosen to span the depth range where low
491 oxygen concentrations exist; these low-oxygen environments are of substantial scientific and
492 societal interest and are sensitive to model formulation. The major features are consistent across
493 the models. Both CanESM models as well as the MEM ~~All three cases~~ show elevated oxygen
494 concentrations relative to observations, particularly in the North Pacific, the North Atlantic and
495 the Southern Ocean. In the Indian Ocean, both CanESM models show high oxygen
496 concentrations in the Arabian Sea and deeper layers of the Bay of Bengal relative to observations
497 and ~~other CMIP6 models~~ the MEM; these biases are somewhat smaller in CanESM5-CanOE than
498 in CanESM5 (Figure 2).

499
500 The ocean's oxygen minimum zones (OMZs) are mostly located in the eastern Pacific Ocean, the
501 northern North Pacific, and the northern Indian Ocean; the spatial pattern changes with
502 increasing depth (Figure 2), but the OMZs are mostly located between 200 and 2000 m depth.

503 Biases in the ~~eastern boundary current~~ EBC regions are depth and model specific. CanESM5
504 shows particularly strong oxygen depletion at 1400 m in the eastern tropical Pacific. In the
505 southeastern Atlantic, models tend to be biased low at the shallower depths, and show somewhat
506 more variation at greater depths (Figure 2). Overall, [O₂] biases tend to be positive over large
507 areas of ocean with the exception of some ~~eastern boundary current~~ EBC regions, implying that
508 models exaggerate the extent to which remineralization is concentrated in these regions. An
509 alternate version of Figure 2 that shows the modelled concentrations ~~model errors relative to the~~
510 ~~observational data product~~ is given in Supplementary Figure S3S2.

511

512 The zonal mean oxygen concentration, saturation concentration, and apparent oxygen utilization
513 (AOU) are shown in Figure 3 for the same four cases. Again, the models generally show a
514 positive bias in $[O_2]$, particularly in high-latitude deep waters. The major ocean circulation
515 features are reproduced fairly well in all cases (e.g., weaker ventilation of low-latitude
516 subsurface waters, greater vertical extent of well-ventilated surface waters in the subtropics). The
517 saturation concentration (a function of temperature and salinity) generally shows relatively little
518 bias, implying that the bias in $[O_2]$ arises mainly from remineralization and/or ventilation. AOU
519 is lower than observed over much of the subsurface ocean. Regional biases are quite consistent
520 across models, but are slightly greater in CanESM5 than in CanESM5-CanOE or the [ensemble](#)
521 [meanMEM](#), except in the Arctic Ocean. Again, Supplementary Figure S23 includes a version of
522 this plot that shows the modelled [differences from the observations concentration fields](#).

523
524 The skill of each model with respect to the distribution of O_2 at different depths is represented by
525 Taylor diagrams (Taylor, 2001) in Figure 4. [These diagrams allow us to assess how well the](#)
526 [model reproduces the spatial distribution at a range of depths, because different physical and](#)
527 [biogeochemical processes determine the distribution in different depth ranges, in which, all](#)
528 of the CMIP6 models that were shown as an ensemble mean in Figures 2 and 3 are shown
529 individually. The [large](#) blue dots represent CanESM5, red CanESM5-CanOE, and grey the
530 [ensemble mean of all CMIP6 models except CanESM5 and CanESM5-CanOEMEM](#); the smaller
531 grey dots represent the individual models. CanESM5-CanOE shows slightly higher pattern
532 correlation than CanESM5 at all depths. Both models compare favourably with the full suite of
533 CMIP6 models, with $r > 0.85$ for CanESM5 and $r > 0.9$ for CanESM5-CanOE at all depths
534 examined, and a normalized standard deviation within $\pm 25\%$ of unity.

535

536 The total volume of ocean with $[O_2]$ less than 6 mmol m^{-3} (the threshold for denitrification
537 (Devol, 2008)) and 60 mmol m^{-3} (a commonly used index of hypoxia) is shown in Figure 5. The
538 total volume is highly variable among models (note, however, that there are several clusters of
539 related models with quite similar totals). CanESM5 and CanESM5-CanOE have among the
540 lowest total volumes (i.e., the interior ocean is relatively well ventilated) and are among the
541 nearest to the observed total. For $[O_2] < 60 \text{ mmol m}^{-3}$ the bias is, nonetheless, quite large (i.e., the
542 observed volume is underestimated by almost 50% in both models). The volume of water with
543 $[O_2]$ below the denitrification threshold is overestimated in both CanESM5 and CanESM5-
544 CanOE; CanESM5-CanOE has a much smaller total that is closer to the observed value. The bias
545 in the spatial pattern of hypoxia (not shown) is generally similar to the bias in dissolved oxygen
546 distribution (Figure 2). The low-oxygen regions are generally more concentrated in the eastern
547 tropical Pacific in the models than in observations, and the low-oxygen region in the northwest
548 Pacific is not well reproduced in CanESM models.

549

550 **3.2 Distribution of DIC, alkalinity, and $CaCO_3$ saturation**

551

552 The spatial distribution of aragonite saturation state (Ω_A) at selected depths is shown in Figure 6.
553 ~~(The first two depths are the same as in Figure 2, but~~ [a much greater depth is also included, as](#)
554 [the length scale for \$CaCO_3\$ dissolution is greater than for organic matter remineralization](#) ~~the~~
555 [third is much deeper](#)). In this case the observations are a combination of GLODAPv2 (Key et al.,
556 [2015](#); Lauvset et al., 2016) for DIC and alkalinity, and WOA20132018 for temperature and
557 salinity. CanESM5 and CanESM5-CanOE generally compare well with other models and

558 observations. The low saturation bias in the eastern tropical Pacific is substantially reduced in
559 CanESM5-CanOE compared to CanESM5. On the other hand CanESM5 generally does better
560 than CanESM5-CanOE, or the [ensemble-meanMEM](#), at reproducing the low saturation states in
561 the northwestern Pacific and the Bering Sea. Both [CanESM](#) models show a high saturation state
562 bias in the North Atlantic and the well-ventilated regions of the north Pacific subtropical gyre;
563 ~~These these~~ biases are ~~reduced~~ slightly [smaller](#) in CanESM5-CanOE, ~~probably due to the smaller~~
564 ~~average remineralization length scale for organic detritus~~. [Maps of the calcite and aragonite](#)
565 [saturation horizon \(\$\Omega=1\$ \) depth are shown in Supplementary Figure S3; these generally confirm](#)
566 [the same biases noted in Figure 6.](#)

567
568 Zonal mean distributions of aragonite saturation state (Ω_A), calcite saturation state (Ω_C), and
569 carbonate ion concentration ($[CO_3^{2-}]$) [and the differences of the models from the observations](#) are
570 shown in Figure 7 (Supplementary Figure [S3-S2](#) includes versions of Figures 6 and 7 that
571 [explicitly](#) show the model ~~led fields~~ ~~differences from the observations~~). The models generally
572 compare well with the observations in the representation of the latitude/depth distribution of high
573 and low saturation waters. CanESM5 has a high saturation bias in low-latitude surface waters
574 that is somewhat reduced in CanESM5-CanOE. Both CanESM5 models show a high saturation
575 bias in Northern Hemisphere intermediate (e.g., 200-1000 m) depth waters that is larger than in
576 the ~~ensemble-meanMEM~~. [This is primarily a result of low \$\Omega\$ in the North Atlantic Ocean \(Figure](#)
577 [6\).](#)

578
579 Taylor diagrams for a range of depths are shown for DIC in Figure 8 and for Ω_A in Figure 9 (for
580 alkalinity, see Supplementary Figure [S42](#)). As expected, the MEM generally compares

581 favourably with the individual models (e.g., Lambert and Boer, 2001). CanESM5 and
582 CanESM5-CanOE compare favourably with the full suite of CMIP6 models. CanESM5-CanOE
583 shows a gain in skill relative to CanESM5, and both show improvement relative to CanESM2. At
584 400 m, CanESM2 stands out as having extremely high variance, which is mostly due to
585 extremely high DIC concentrations occurring over a limited area in the eastern equatorial Pacific
586 (not shown). This bias is present in CanESM5 and in CMIP6 models generally (Figure 6) but
587 involves much lower concentrations spread over a larger area.

588

589 **3.3 N and Fe cycles**

590

591 An important difference between ~~CMOC-CanESM5~~ and ~~CanESM5-CanOE~~ is the inclusion of a
592 prognostic Fe cycle. The CMOC iron mask (Zahariev et al., 2008) was a pragmatic solution in
593 the face of resource limitations but is inherently compromised as it can not evolve with a
594 changing climate. ~~Other centres that introduced a prognostic Fe cycle between CMIP5 and~~
595 ~~CMIP6 include JAMSTEC (MIROC-ESM, MIROC-ES2L) and the UK Met Office (HadGEM2-~~
596 ~~ES, UKESM1-0-LL).~~ The first order test of a model with prognostic, interacting Fe and N cycles
597 is whether it can reproduce the distribution of ~~High-Nutrient, Low-Chlorophyll~~ (HNLC) regions
598 and the approximate surface macronutrient concentrations within these. CanESM5-CanOE
599 succeeded by this standard, although the surface nitrate concentrations are biased low in the
600 subarctic Pacific and equatorial Pacific and high in the Southern Ocean and in the global mean
601 (Figure 10).

602

603 The seasonal cycle of the zonal mean surface nitrate concentration for a selection of CMIP6

604 models is shown in Figure 11. CanESM5, CanESM5-CanOE, and CNRM-ESM2-1 reproduce the
605 equatorial enrichment and the low concentrations in the tropical-subtropical latitudes fairly well.
606 Some models either have very weak equatorial enrichment (MPI-ESM1-2-LR) or too high a
607 concentration in the off-equatorial regions (UKESM1-0-LL, NorESM2-LM). UKESM1-0-LL
608 has very high concentrations throughout the low-latitude Pacific, which biases the ensemble
609 mean (Figure 11a). [Supplementary Figure S611b](#) shows the same data as Figure 11a but for a
610 more limited latitude range to better illustrate model behaviour in the tropics. CanESM5,
611 CanESM5-CanOE, and CNRM-ESM2-1 reproduce the seasonal cycle of tropical upwelling (e.g.,
612 Philander and Chao, 1991), with highest concentrations in summer.

613
614 The surface distribution of dissolved iron (dFe) in various CMIP6 models is shown in Figure 12.
615 For Fe there is no observation-based global climatology with which to compare the model
616 solutions (some comparisons to available profile data are shown in Supplementary Figures
617 [S4bS9b-gh](#)). CanESM5-CanOE shows a similar overall spatial pattern to other models, and
618 generally falls in the middle of the spread, particularly regarding concentrations in the Southern
619 Ocean. Several models show extremely high concentrations in the tropical-subtropical North
620 Atlantic (Sahara outflow region). CanESM5-CanOE, along with CNRM-ESM2-1 and CESM2,
621 has much less elevated concentrations in this region, due to lower deposition or greater
622 scavenging or both. CanESM5-CanOE has its lowest concentration in the eastern subtropical
623 South Pacific, which is common to many models (Figure 12). The area of strong surface
624 depletion is generally more spatially restricted in CanESM5-CanOE than in other models, and
625 surface dFe concentrations are greater over large areas of the Pacific. Both the north-south and
626 east-west asymmetry of distribution in the Pacific is greater in CanESM5-CanOE than in most

627 other models, some of which show the South Pacific minimum extending westward across the
628 entire basin, and others into the Northern Hemisphere. Only in CESM2 is this minimum
629 similarly limited to the southeast Pacific.

630
631 The mean depth profiles of dFe are shown in Figure 13. Some models show more of a “nutrient-
632 type” (increasing with depth due to strong near-surface biological uptake and subsequent
633 remineralization) profile, some a more “scavenged-type” (maximal at the surface, declining with
634 depth) profile (cf. Li, 1991; Nozaki, 2001), and others a hybrid profile (increasing downward but
635 with a surface enrichment). CanESM5-CanOE is at the “nutrient-type” end of spectrum with a
636 generally monotonic increase with depth to a near-constant deep-water concentration of 0.6 nM
637 and a very slight near-surface enrichment (see also Supplementary Figures [S9S4b,c](#)). ~~In~~

638 ~~CanESM5-CanOE the scavenging model is very simple, with distinct regimes for concentrations~~
639 ~~greater or less than 0.6 nM; scavenging rates are very high above this threshold which causes~~
640 ~~deep water concentrations to converge on this value. The generally nutrient-like profile suggest~~
641 ~~that in CanOE the scavenging rate is quite low for concentrations below 0.6 nM. CanOE~~
642 ~~considers particulate organic matter (POM) as an index of all particulate matter available for~~
643 ~~scavenging onto, and model POM concentrations fall off rapidly below the euphotic zone (not~~
644 ~~shown).~~

645
646 Mean surface nitrate and dFe concentrations for selected ocean regions are shown in Figure 14.
647 CanESM5-CanOE shows concentrations that are within the range of CMIP6 models, although in
648 some cases at the higher or lower end. Surface nitrate concentrations generally compare
649 favourably with the observation-based climatology, but are biased low in HNLC regions other

650 than the Southern Ocean. These biases are not necessarily a consequence of having too much or
651 too little iron. For example, in the Southern Ocean CanESM5-CanOE has among the highest
652 surface nitrate concentrations, but it also has some of the highest dFe concentrations, and the
653 high nitrate bias is present in CanESM5 as well. Comparisons with the limited GEOTRACES
654 data available suggest that near surface dFe concentrations in the Southern Ocean are biased high
655 rather than low in CanESM5-CanOE (not shown). One region where there does seem to be a
656 strong correlation between surface nitrate and dFe concentrations is the western subarctic
657 Pacific. All but two models ([CNRM-ESM2-1](#), [NorESM2-LM](#)) fall along a spectrum from high
658 Fe / low nitrate to low Fe / high nitrate. CanESM5-CanOE falls near the high Fe / low nitrate end
659 of the range.

660

661 Surface nitrate concentrations along the Pacific equator during the upwelling season (June-
662 October) for CanESM5 and CanESM5-CanOE are shown in Figure 15. [The range of other](#)
663 [CMIP6 models is not shown here because it is large and therefore adds little information \(see](#)
664 [Figure 11 and Supplementary Figure S6\).](#) CanESM5-CanOE better represents the east-west
665 gradient, while CanESM5 has slightly higher concentrations in the core upwelling region. Both
666 models underestimate the highest concentrations around 100°W. ~~Some~~ [Although some](#) localized
667 maxima in this data product are due to undersampling, [equatorial upwelling is strong at this](#)
668 [location \(e.g., Lukas, 2001\) and the spatial coherence of the data strongly suggests that this](#)
669 [maximum accurately reflects reality; however, examination of ancillary data sets such as satellite](#)
670 [sea surface temperature suggests that the enrichment at 100°W accurately reflects ocean](#)
671 [upwelling \(not shown\).](#) ~~Although~~ [It should be noted that](#) CanESM5 iron limitation is calculated
672 from ~~an earlier~~ version of the same data product, ~~;~~ [however,](#) the Fe mask is based on the

673 minimum nitrate concentration over the annual cycle, whereas the data shown here are for the
674 upwelling season. ~~In CanESM5-CanOE, the distribution of surface nitrate is an emergent
675 property of the model, and the fidelity to the observed distribution is generally good.~~

676

677 **3.4 Plankton biomass, detritus, and particle flux**

678

679 The relative abundance of the four living plankton groups are shown in Figure 16 for a range of
680 ocean regions. Both CanESM models mostly compare favourably with observation-based
681 estimates of phytoplankton biomass, except in the tropics where CanESM5-CanOE has very high
682 biomass. Both CanESM models have low phytoplankton biomass in the North Atlantic. In the
683 North Pacific and the Southern Ocean, CanESM5-CanOE reproduces the observation-based
684 estimates well, and CanESM5 slightly less well. The general pattern is that large and small
685 phytoplankton have similar abundance, and are substantially more abundant than zooplankton.

686

687 Part of the rationale for multiple food chains is that they better represent the way that actual
688 plankton communities adapt to different physical ocean regimes and therefore are better able to
689 simulate distinct ocean regions with a single parameter set (e.g., Chisholm, 1992; Armstrong,
690 1994; Landry et al., 1997; Friedrichs et al., 2007). The expectation is that small phytoplankton
691 will be more temporally stable and large phytoplankton will fluctuate more strongly between
692 high and low abundances. The mean annual cycles of surface chlorophyll largely conform to
693 ~~this expected~~ pattern, e.g., in the North Atlantic and the western subarctic Pacific large
694 phytoplankton are dominant in summer and much more variable over the seasons (Figure 17).

695 Compared to observations, CanESM5 models underestimate the amplitude of the seasonal cycle

696 in the North Atlantic and overestimate it in the North Pacific. CanESM5 shows a stronger and
697 earlier North Atlantic spring bloom compared to CanESM5-CanOE; the observations are in
698 between the two in terms of timing, and both models underestimate the amplitude (Figure 17). In
699 the tropics, the seasonal cycle is weak. ~~CanESM5-CanOE in T~~the tropical Atlantic shows the
700 expected seasonal cycle but not the expected dominance of large phytoplankton in summer.
701 ~~These size-fractionation patterns are difficult to validate against observations.~~CanESM5-CanOE
702 generally overestimates the total near surface chlorophyll in both the tropical Pacific and the
703 tropical Atlantic.

704
705 Zooplankton biomass (especially microzooplankton) is also somewhat difficult to test against
706 observations, but our model concentrations appear to be biased low. ~~White et al. (1995), for~~
707 ~~example, show a transect of vertically resolved mesozooplankton abundance along 140°W in the~~
708 ~~tropical Pacific, with biomass ranging from about 0.1–0.7 mmolC m⁻³; CanESM5-CanOE~~
709 ~~concentrations in this region are much lower.~~Stock et al. (2014) estimated depth-integrated
710 biomass of phytoplankton, mesozooplankton, and microzooplankton for a range of oceanic
711 locations in which intensive field campaigns have occurred (estimates of microzooplankton
712 biomass are relatively sparse). They found that in most locations phytoplankton and (combined)
713 zooplankton biomass are of comparable magnitude, whereas in CanESM5-CanOE zooplankton
714 biomass is consistently lower (Figure 16). The global integral biomass of mesozooplankton is
715 about an order of magnitude less than the 0.19 PgC estimated by Moriarty and O'Brien (2013).
716 The CanESM5 total of 0.14 Pg is relatively close to the Moriarty estimate but implicitly includes
717 microzooplankton.

718

719 Surface chlorophyll and POC for CanESM5-CanOE and for ocean colour observational data are
720 shown in Figure 18 (POC in the model is the sum of phytoplankton, microzooplankton, and
721 detrital carbon). The observations have a lower limit for POC that is not present in the model
722 ($\sim 17 \text{ mgC m}^{-3}$), which is unsurprising given the processes neglected in the model, i.e., in regions
723 of very low chlorophyll there is still substantial dissolved organic carbon, bacteria that consume
724 it, and microzooplankton that consume the bacteria and produce particulate detritus. The
725 observational data show a fairly linear relationship at low concentrations, but with a curvature
726 that implies a greater phytoplankton fraction in more eutrophic environments (cf. Chisholm,
727 1992). The model, by contrast, shows a fairly linear relationship over the whole range of
728 concentrations. In other words, the phytoplankton share of POC is higher and more constant in
729 the model than in the observations. The living biomass (phytoplankton + microzooplankton)
730 fraction of total POC in CanOE is generally in excess of 50% (not shown), which is implausible
731 for a real-world oceanic microbial community (e.g., Christian and Karl, 1994) but consistent
732 with the relatively low rates of export from the euphotic zone.

733
734 Export production for a range of CMIP6 models is shown in Figure 19a. CanESM5-CanOE is at
735 the low end of the range. Observations are not shown because the range of observational
736 estimates covers almost the entire range of the plot model estimates (e.g., Siegel et al., 2016).

737 Note also that CanESM5 export is quite a bit lower than in CanESM2, which is relatively high
738 for CMIP5 models (not shown). The difference between CanESM2 and CanESM5 is attributable
739 primarily to different circulation, although the different initialization fields for nitrate might also
740 play a small role. The lower rate in CanESM5-CanOE is consistent with the above results
741 regarding plankton community structure (e.g., the concentration of detritus is generally low

742 compared to living biomass), as well as the lower sinking rate for small detritus. The latitudinal
743 distribution of export is shown in Figure 19b. CanESM5 shows very high export in the mid-
744 latitudes of the Southern Ocean, similar to CanESM2 (not shown). Both CanESM5 [and](#)
745 [CanESM5-CanOE models](#) show latitudinal patterns consistent with the range of other [CMIP6](#)
746 models. CanESM5 has slightly greater export in the equatorial zone; in both CanESM5 [and](#)
747 [CanESM5-CanOE models](#) the equatorial enrichment attenuates very rapidly with latitude and the
748 rates are low in the subtropics.

749

750 **3.5 Historical trends**

751

752 Cumulative ocean uptake of CO₂ is shown in Figure 20 for the historical experiment (1850-
753 2014). CanESM models are biased low relative to observation based estimates (~145 PgC, see
754 Friedlingstein et al., 2020) and the [ensemble mean of other models MEM](#) (144 PgC, Figure 20),
755 but fall well within the spread of CMIP6 models. CanESM5-CanOE has lower cumulative
756 uptake than CanESM5 by ~10 PgC. As the models were not fully equilibrated when the
757 historical run was launched, this difference does not necessarily arise from the biogeochemical
758 model structure; part of the difference can be attributed to differences in the spinup protocol (cf.
759 Séférian et al., 2016). The drift in the piControl experiment over the 165 years from the
760 branching off of the historical experiment is -10.5-0 PgC in CanESM5-CanOE and -5.9-1 PgC in
761 CanESM5 ([see Supplementary Table S6](#)), so drift accounts for about half (48%) of the
762 difference in net ocean CO₂ uptake. The [vertical-spatial](#) distribution of anthropogenic DIC is
763 very similar between CanESM5 and CanESM5-CanOE ([not shown Supplementary Figure S7](#)).

764

765 The long-term trend in global total export production is shown in Figure 21. The model values
766 must be normalized in order to compare trends, since the differences among means are large
767 compared to the changes over the historical period (Figure 19). Such trends are difficult or
768 impossible to meaningfully constrain with observations, but the general expectation has been that
769 export will decline somewhat due to increasing stratification (e.g., Steinacher et al., 2010).
770 CanESM5 shows a greater decline than most other CMIP6 models, while CanESM5-CanOE is
771 more similar to non-CanESM models. ~~Such trends are difficult or impossible to meaningfully~~
772 ~~constrain with observations, but the general expectation has been that export will decline~~
773 ~~somewhat due to increasing stratification (e.g., Steinacher et al., 2010).~~ The change in CanESM5
774 is geographically widespread and not concentrated in a specific region or regions: export is
775 maximal in the tropics and the northern and southern mid-latitudes (Figure 19b) and declines
776 over the historical period in all of these regions (Supplementary Figure S81). In CanESM5-
777 CanOE, export declines in the same regions, but the magnitude of the change is smaller, and in
778 the Southern Ocean increases and decreases in different latitude bands largely offset each other.
779

780 The trend in the volume of ocean water with O₂ concentration less than 6 or 60 mmol m⁻³ is
781 shown in Figure 22. Again, the totals are normalized to a value close to the preindustrial, as the
782 differences among models are large (Figure 5). For the volume with <60 mmol m⁻³, CanESM
783 models show relatively little change; in CanESM5 the volume actually declines slightly, while in
784 CanESM5-CanOE it increases, but the total change is <1% in each case. As with the baseline
785 volumes, the range among models is large, with one model showing an increase approaching
786 10% of the total volume estimated for WOA20132018 (Figures 5b and 22b). For the volume
787 with <6 mmol m⁻³ (Figure 22a), CanESM models are among the most stable over time. In

788 CanESM5, the volume again declines, although this is within the range of internal variability.
789 Again some models show fairly large excursions, but in this case none shows a strong secular
790 trend over the last half-century.

791

792 **4. Discussion**

793

794 CanESM5 and CanESM5-CanOE are new coupled ocean-atmosphere climate models with
795 prognostic ocean biogeochemistry. The two have the same physical climate (in experiments with
796 specified atmospheric CO₂) and differ only in their ocean biogeochemistry components.
797 CanESM5-CanOE has a much more complex biogeochemistry model including a prognostic iron
798 cycle. We have presented results that assess how these two models simulate the overall
799 distribution of major tracers like DIC, alkalinity, nitrate and oxygen, as well as analyses of the
800 interaction of the iron and nitrogen cycles, plankton community structure, export of organic
801 matter from the euphotic zone, and historical trends over 1850-2014.

802

803 The overall distribution of major tracers indicates that both models do a reasonable job of
804 simulating both biogeochemical (e.g., export and remineralization of organic matter) and
805 physical (e.g., deep and intermediate ocean ventilation) processes. The volume of ocean with
806 oxygen concentration below 6 or 60 μM compares favourably with other CMIP6 models (Figure
807 5), and is among the most stable over historical time (Figure 22). CanESM5-CanOE has a
808 substantially lower volume of water with [O₂] $<$ 6 μM than CanESM5 and much closer to
809 observation-based estimates (Figure 22a). Both models are biased slightly low in terms of
810 historical uptake of anthropogenic CO₂, which may indicate weak Southern Ocean upwelling or

811 too shallow remineralization of DIC or both (Figure 20). The spatial distribution of
812 anthropogenic DIC is very similar between the two models (Supplementary Figure S7), which is
813 expected as it is mainly a function of the physical ocean model circulation. However, CanESM5
814 has higher concentrations in the main areas of accumulation, particularly the North Atlantic and
815 the Southern Ocean. This probably indicates more efficient removal and export of 'natural' DIC
816 by the plankton, particularly in the Southern Ocean upwelling zone (Figure 19), and deeper
817 average remineralization, with the caveat that the preindustrial control simulations had different
818 degrees of equilibration when the historical experiment was launched (cf. Séférian et al., 2016,
819 Supplementary Table S6).

820
821 Analysis of phytoplankton and zooplankton biomass concentrations show that CanESM5 and
822 CanESM5-CanOE compare somewhat favourably with available observational data but do have
823 distinct biases. In particular, both zooplankton biomass and detrital organic matter concentration
824 tend to be very low in CanESM5-CanOE; the total biomass of the plankton community and the
825 standing crop of particulate organic matter are dominated by phytoplankton (e.g., Figure 17).
826 Regional biases differ between the two models, with CanESM5-CanOE showing excessively
827 large phytoplankton biomass in the tropics. We note, however, that the seasonal cycle of
828 equatorial upwelling and the formation of the equatorial Pacific HNLC are reproduced rather
829 well by our models (e.g., Figures 11, 15 and S6), and that CanESM5-CanOE is the first CanESM
830 model to have genuinely simulated this as an emergent property (see section 3.3). In CanESM5-
831 CanOE, decoupling of large and small phytoplankton populations associated with seasonal
832 upwelling or convection (see below) is observed in some regions but not others.

833

834 [Global export production is biased low, particularly in CanESM5-CanOE. This is due in part to](#)
835 [the biogeochemical model and in part to ocean circulation. CanESM5 has the same ocean](#)
836 [biology as CanESM2 but a different physical ocean model, and global ocean export production is](#)
837 [substantially lower in CanESM5. It is lower still in CanESM5-CanOE \(Figure 19\). We note that](#)
838 [CanESM5 performs better than CanESM2 on most metrics of physical ocean model evaluation](#)
839 [\(Swart et al., 2019a\), and shows a more realistic distribution of major tracers like DIC \(Figure 8\).](#)
840 [While the range of observation-based estimates of global ocean export production is large, and](#)
841 [encompasses the full range of CMIP5 and CMIP6 models, the change between CanESM2 and](#)
842 [CanESM5 is large. Changes in the physical ocean are not entirely independent of the](#)
843 [biogeochemistry model even when the latter is ostensibly identical. In CanESM2 and CanESM5,](#)
844 [iron limitation is specified as a spatially static 'mask' based on the observed distribution of](#)
845 [surface nitrate, and it is possible that in these two models ocean upwelling occurs in different](#)
846 [places relative to the specified boundary of the region of Southern Ocean iron imitation \(Figure 3](#)
847 [of Zahariev et al., 2008\). It is also possible that the lower export production in CanESM5-CanOE](#)
848 [is due to low iron supply to the surface waters of the Southern Ocean, but comparison with](#)
849 [available observations do not suggest that this is the case. Several biases are common to](#)
850 [CanESM5 and CanESM5-CanOE that relate to Southern Ocean upwelling \(high Southern Ocean](#)
851 [surface nitrate concentration, low export production, weak anthropogenic CO₂ uptake\) and so are](#)
852 [probably more attributable to the physical ocean model than to the Fe submodel. The difference](#)
853 [between CanESM2 and CanESM5 bears this out.](#)

854

855 The development of CanOE was undertaken in response to some of the most severe limitations
856 of CanESM4/2, and in light of our collective experience. In addition to CMOC (Zahariev et al.,

857 2008), previous models developed by members of our group include Denman and Peña (1999;
858 2002), Christian et al. (2002a; 2002b), Christian (2005), and Denman et al. (2006). Christian et
859 al. (2002a) had a prognostic Fe cycle and multiple phytoplankton and zooplankton species, but
860 had fixed elemental ratios. Christian (2005) incorporated a cellular-regulation model, but only
861 for a single species and without Fe limitation. Christian (2005) had prognostic chlorophyll
862 whereas Denman and Peña (1999; 2002) and Christian et al. (2002a) used an irradiance-
863 dependent diagnostic formulation. Christian et al. (2002a) used multiplicative (Franks et al.,
864 1986) grazing, which creates stability in predator-prey interactions but severely limits
865 phytoplankton biomass accumulation under nutrient-replete conditions.

866

867 One of the most important lessons from Christian et al. (2002a; 2002b) was that when a fixed
868 Fe/N ratio is employed, sensitivity to this parameter is extreme. Because Fe cell quotas are far
869 more variable than N, P, or Si quotas, treating this parameter as constant results in the specified
870 value influencing the overall solution far more than any other parameter. CanESM5-CanOE
871 largely succeeded in creating a prognostic Fe-N limitation model that produces HNLC conditions
872 in the expected regions (Figures 10, 11, 14, 15, [S6](#)), although surface nitrate concentration is low
873 relative to observation-based estimates in some cases. External Fe sources and scavenging
874 parameterizations will be revisited and refined in future versions. [In CanESM5-CanOE the](#)
875 [scavenging model is very simple, with distinct regimes for concentrations greater or less than 0.6](#)
876 [nM; scavenging rates are very high above this threshold which causes deep-water concentrations](#)
877 [to converge on this value. The generally nutrient-like profile suggest that in CanOE the](#)
878 [scavenging rate is quite low for concentrations below 0.6 nM \(Figure 13; see also Supplementary](#)
879 [Figure S9h\)](#). We note that the aeolian mineral dust deposition field employed here is derived

880 from the CanESM atmosphere model; these processes are not presently interactive but could be
881 made so in the future.

882

883 A particular issue with CanESM2 was that extremely high concentrations of nitrate occurred
884 under the [Eastern Boundary Current \(EBC\)](#) upwelling regions. This error resulted from
885 spreading denitrification out over the ocean basin so that introduction of new fixed N from N₂
886 fixation would balance denitrification losses within each vertical column, whereas in the real
887 world denitrification is highly localized in the low oxygen environments under the EBCs.

888 CanESM2 did not include oxygen, but CanESM5 [CMOC](#) incorporates oxygen as a ‘downstream’
889 tracer that does not feed back on other biogeochemical processes. The incorporation of a more
890 process-based denitrification parameterization in [CanESM5-CanOE](#) is independent of the many
891 other processes that are present in [CanESM5-CanOE](#) but not in [CanESM5CMOC](#): a CMOC-like
892 model with prognostic denitrification is clearly an option. We chose not to include explicit,
893 oxygen-dependent denitrification in CanESM5 because we wanted to maintain a CMOC-based
894 model as close to the CanESM2 version as possible, and because oxygen would not then be a
895 downstream tracer that does not affect other processes.

896

897 ~~CanOE for the most part successfully reproduces the overall distribution of major tracers such as~~
898 ~~nitrate, oxygen, DIC and alkalinity (and dFe, to the extent that its distribution is known). One~~
899 ~~could argue that the gains made relative to CMOC are incremental. However, it is also important~~
900 ~~to note that CanOE explicitly simulates important processes that are highly parameterized or~~
901 ~~specified in CMOC. For example, the maintenance of HNLC regions is hardwired into CMOC~~
902 ~~by specifying iron limitation as a function of the present day observed distribution of surface~~

903 ~~nitrate. Both models show substantial gains in skill relative to CanESM2. These gains are similar~~
904 ~~in the two models and in coupled or ocean-only (with CanESM2 forcing) mode (not shown) and~~
905 ~~are, therefore, attributable primarily to improvements in the ocean circulation model, although~~
906 ~~differences in initialization and spinup may also play a small role (e.g., Séférian et al., 2016).~~

907

908 Plankton community structure in [CanESM5-CanOE](#) is somewhat biased toward high
909 concentrations of phytoplankton, low concentrations of zooplankton and detritus, and low export
910 (Sect. 3.4). In the development phase, a fair number of experiments were conducted with various
911 values of the grazing rates and detritus sinking speeds. A wide range of values of these
912 parameters was tested, with no resulting improvement in the overall results. Possibly the detrital
913 remineralization rates are too high, although primary production is also on the low end of the
914 CMIP6 range (not shown), and would probably decline further if these rates were decreased. The
915 model was designed around the Armstrong (1994) hypothesis of ‘supplementation’ vs
916 ‘replacement’, i.e., small phytoplankton and their grazers do not become much more abundant in
917 more nutrient-rich environments but rather stay at about the same level and are joined by larger
918 species that are absent in more oligotrophic conditions (see also Chisholm, 1992; Landry et al.,
919 1997; Friedrichs et al., 2007). The results presented here suggest that this was partially achieved
920 but further improvement is possible (Figure 17).

921

922 As to whether the gains in skill with [CanESM5-CanOE](#) justify the extra computational cost,
923 Taylor diagrams (Figures 4, 8, 9, and Supplementary Figure [S2S4](#)) show a modest but consistent
924 gain [in skill at simulating the major biogeochemical species \(O₂, DIC, alkalinity\)](#) across
925 variables and depths, especially for alkalinity at mid-depths (Supplementary Figure [S2S4](#)), for

926 which CanESM5 displays the least skill relative to other fields or depths. Other processes that are
927 highly parameterized in [CanESM5CMOC](#), such as calcification and CaCO₃ dissolution, were not
928 addressed in detail in this paper, but are an important factor in determining the subsurface
929 distribution of alkalinity. ~~As noted above for maintenance of HNLC conditions, Again,~~ we
930 emphasize that we are simulating as an emergent property something that is parameterized in
931 [CanESM5CMOC \(as previously noted for surface nitrate concentration in HNLC regions\)](#), and
932 doing at least as well in terms of model skill. As a general rule, the potential for improving skill
933 and achieving better results in novel environments (e.g., topographically complex regional
934 domains like the Arctic Ocean and the boreal marginal seas), is expected to be greater in less
935 parameterized models (e.g., Friedrichs et al., 2007; Tesdal et al., 2016).

936

937 An updated version of [CanESM5CMOC](#) with prognostic denitrification is clearly possible.
938 However, for the reasons discussed above, a prognostic Fe cycle with a fixed phytoplankton
939 Fe/N remains problematic, and the model would still have a single detritus sinking speed and
940 remineralization length scale. We are also developing CanOE for regional downscaling
941 applications (Hayashida, 2018; Holdsworth et al., 2021), and it is likely that the simplification of
942 having a single particle sinking speed is not well suited to a domain with complex topography
943 and prominent continental shelf and slope. The number of tracers in CanOE is not particularly
944 large compared with other CMIP6 models. We expect to further refine CanOE and its
945 parameterizations, evaluate it against new and emerging ocean data sets (e.g., GEOTRACES,
946 biogeochemical Argo), and incrementally improve CMOC (which we will maintain for a wide
947 suite of physical-climate experiments for which ocean biogeochemistry is not central to the
948 purpose). For CMIP6, we chose to keep CMOC as close to the CanESM2 version as possible.

949 This strategy allows us to quantify how much of the improvement in model skill is due to the
950 physical circulation, ~~which is in fact substantial~~ [as is illustrated by greater skill with respect to](#)
951 [DIC \(e.g., Figure 8\)](#) [and alkalinity \(Supplementary Figure S4\), particularly at intermediate depths](#)
952 [\(400-900 m\)](#). The CanESM terrestrial carbon model is also undergoing important new
953 developments (e.g., Asaadi and Arora, 2021) and we expect CanESM to continue to offer a
954 credible contribution to global carbon cycle studies, as well as advancing regional downscaling
955 and impacts science.

956

957 *Code availability.* The full CanESM5 source code is publicly available at
958 gitlab.com/ccma/canesm; within this tree the [CMOC/CanOE ocean biogeochemistry](#) code can
959 be found at [gitlab.com/ccma/cannemo/-](https://gitlab.com/ccma/cannemo/-/tree/v5.0.3/nemo/CONFIG/CCC_CANCP_L_ORCA1_LIM_CMOC)
960 [/tree/v5.0.3/nemo/CONFIG/CCC_CANCP_L_ORCA1_LIM_CMOC](#) or
961 [CCC_CANCP_L_ORCA1_LIM_CANOE](#) (last access: 21 September 2021). The version of the
962 code which can be used to produce all the simulations submitted to CMIP6, and described in this
963 paper, is tagged as v5.0.3 and has the associated DOI: <https://doi.org/10.5281/zenodo.3251113>
964 (Swart et al., 2019b).

965

966 *Data availability.* All ~~CanESM5~~ simulations conducted for CMIP6, including those described in
967 this paper, are publicly available via the Earth System Grid Federation ~~(ESGF)~~ [\(source_id =](#)
968 [CanESM5 or CanESM5-CanOE\)](#). All observational data and other CMIP6 model data used are
969 publicly available.

970

971 *Author contributions.* Formulation of the overall research goals and aims: JRC, KLD, NS, NCS;
972 Implementation and testing of the model code: JRC, HH, AMH, WGL, OGJR, AES, NCS;
973 Carrying out the experiments: JRC, WGL, OGJR, AES, NCS; Creation of the published work:
974 JRC, HH, AMH, AES, NS, NCS.

975

976 *Competing interests.* The authors declare that they have no conflict of interest.

977

978 *Disclaimer.* CanESM has been customized to run on the ECCC high-performance computer, and
979 a significant fraction of the software infrastructure used to run the model is specific to the
980 individual machines and architecture. While we publicly provide the code, we cannot provide
981 any support for migrating the model to different machines or architectures.

982

983 *Acknowledgments.* This work was made possible by the combined efforts of the CCCMa model
984 development team and computing support team. We thank [all of the](#) the data contributors to and
985 developers of the [observational-based](#) data products, the NASA ocean colour team, and all of the
986 CMIP6 data contributors. The Python packages *mocsy* by Jim Orr and *SkillMetrics* by Peter
987 Rochford were invaluable tools in the analysis. William Merryfield and Andrew Ross made
988 useful comments on an earlier draft. [Fiona Davidson helped with figure preparation.](#) This paper
989 is dedicated to the memory of Mr. Fouad Majaess, who supported CCCMa supercomputer users
990 for many years and passed away suddenly in 2020.

Table 1 – Ecosystem model parameters.

Symbol	Description	Unit	
T_{ref}	Reference temperature	K	298.15
E_{ap}	Activation energy for photosynthesis	kJ mol^{-1}	37.4
$Q_{\text{mins}}^{\text{N}}$	Small phytoplankton minimum N quota	g N g C^{-1}	0.04
$Q_{\text{maxs}}^{\text{N}}$	Small phytoplankton maximum N quota	g N g C^{-1}	0.172
$Q_{\text{minl}}^{\text{N}}$	Large phytoplankton minimum N quota	g N g C^{-1}	0.04
$Q_{\text{maxl}}^{\text{N}}$	Large phytoplankton maximum N quota	g N g C^{-1}	0.172
$Q_{\text{mins}}^{\text{Fe}}$	Small phytoplankton minimum Fe quota	$\mu\text{g Fe g C}^{-1}$	4.65
$Q_{\text{maxs}}^{\text{Fe}}$	Small phytoplankton maximum Fe quota	$\mu\text{g Fe g C}^{-1}$	93.
$Q_{\text{minl}}^{\text{Fe}}$	Large phytoplankton minimum Fe quota	$\mu\text{g Fe g C}^{-1}$	6.5
$Q_{\text{maxl}}^{\text{Fe}}$	Large phytoplankton maximum Fe quota	$\mu\text{g Fe g C}^{-1}$	70.
$V_{\text{ref}}^{\text{N}}$	Reference rate of N uptake	$\text{g N g C}^{-1} \text{d}^{-1}$	0.6
$V_{\text{ref}}^{\text{Fe}}$	Reference rate of Fe uptake	$\mu\text{g Fe g C}^{-1} \text{d}^{-1}$	79.
$P_{\text{ref}}^{\text{C}}$	Reference rate of photosynthesis	$\text{g C g C}^{-1} \text{d}^{-1}$	3
k_{XU}	Rate coefficient for exudation	d^{-1}	1.7
k_{dgr}	Rate coefficient for chlorophyll degradation	d^{-1}	0.02
ζ	Respiratory cost of biosynthesis	g C g N^{-1}	2
α_{chl}	Initial slope of P-E curve	$\text{g C g CHL}^{-1} \text{h}^{-1} (\mu\text{mol m}^{-2} \text{s}^{-1})^{-1}$	1.08
$\Theta_{\text{max}}^{\text{N}}$	Maximum chlorophyll-nitrogen ratio	g g^{-1}	0.18
K_{NiS}	Half-saturation for small phytoplankton nitrate uptake	$\text{mmol}^{-1} \text{m}^3$	0.1
K_{NaS}	Half-saturation for small phytoplankton ammonium uptake	$\text{mmol}^{-1} \text{m}^3$	0.05
K_{FeS}	Half-saturation for small phytoplankton iron uptake	$\text{nmol}^{-1} \text{m}^3$	100
K_{NiL}	Half-saturation for large phytoplankton nitrate uptake	$\text{mmol}^{-1} \text{m}^3$	1.0
K_{NaL}	Half-saturation for large phytoplankton ammonium uptake	$\text{mmol}^{-1} \text{m}^3$	0.05
K_{FeL}	Half-saturation for large phytoplankton iron uptake	$\text{nmol}^{-1} \text{m}^3$	200
$m_{1\text{S}}$	Small phytoplankton/zooplankton mortality rate (linear)	d^{-1}	0.05
$m_{2\text{S}}$	Small phytoplankton/zooplankton mortality coefficient	$(\text{mmol C m}^{-3})^{-1} \text{d}^{-1}$	0.06
$m_{1\text{L}}$	Large phytoplankton/zooplankton mortality rate (linear)	d^{-1}	0.1

m_{2L}	Large phytoplankton/zooplankton mortality coefficient	$(\text{mmol C m}^{-3})^{-1} \text{ d}^{-1}$	0.06
X_{minp}	Minimum phytoplankton concentration for linear mortality	mmol C m^{-3}	0.01
a_L	Large zooplankton grazing parameter	$(\text{mmol C m}^{-3})^{-1}$	0.25
G_{L0}	Large zooplankton maximum grazing rate	d^{-1}	0.85
a_S	Small zooplankton grazing parameter	$(\text{mmol C m}^{-3})^{-1}$	0.25
G_{S0}	Small zooplankton maximum grazing rate	d^{-1}	1.7
λ	Assimilation efficiency	n.d.	0.8
r_{Zs}	Microzooplankton specific respiration rate at T_{ref}	d^{-1}	0.3
r_{Zl}	Mesozooplankton specific respiration rate at T_{ref}	d^{-1}	0.1
r_1	Small detritus remineralization rate at T_{ref}	d^{-1}	0.25
r_2	Large detritus remineralization rate at T_{ref}	d^{-1}	0.25
E_{ar}	Activation energy for detritus remineralization	kJ mol^{-1}	54.0
w_s	Small detritus sinking speed	m d^{-1}	2.
w_l	Large detritus sinking speed	m d^{-1}	30.
w_{Ca}	CaCO_3 sinking speed	m d^{-1}	20.
P_{Ca}	CaCO_3 production as fraction of mortality	$\text{mol CaCO}_3 \text{ molC}^{-1}$	0.05
k_{Ca}	CaCO_3 dissolution rate	d^{-1}	0.0074
$S_{\text{Fe}1}$	Dissolved iron scavenging loss rate ($\text{Fe} \leq L_{\text{Fe}}$)	d^{-1}	0.001
$S_{\text{Fe}2}$	Dissolved iron scavenging loss rate ($\text{Fe} > L_{\text{Fe}}$)	d^{-1}	2.5
L_{Fe}	Ligand concentration	nmol Fe m^{-3}	600.
P_{Fe}	POC-dependence parameter for Fe scavenging	$(\text{mmolC m}^{-3})^{-1}$	0.66
$K_{\text{NH}4\text{ox}}$	Nitrification rate in darkness constant	d^{-1}	0.05
K_E	Half-saturation for irradiance inhibition of nitrification	W m^{-2}	1.
k_{dnf}	Light and nutrient saturated rate of N_2 fixation at 30°C	$\text{mmol m}^{-3} \text{ d}^{-1}$	0.0225
a	Initial slope for irradiance-dependence of N_2 fixation	$(\text{W m}^{-2})^{-1}$	0.02
K_{Fe}	Half-saturation for Fe dependence of N_2 fixation	nmol m^{-3}	100.
$K_{\text{NO}3}$	Half-saturation for DIN inhibition of N_2 fixation	mmol m^{-3}	0.1
O_{mxd}	O_2 concentration threshold for denitrification	mmol m^{-3}	6.
A_f	Anammox fraction of N loss to denitrification	n.d.	0.25

Figure 1 - Schematic of the CanOE biology model. Model currencies including chlorophyll (Chl) are indicated by coloured boxes except oxygen (O_2) and carbonate ($CaCO_3$). Arrows indicate flows of carbon (C), nitrogen (N) and iron (Fe) between compartments containing small (S) and large (L) phytoplankton (P), zooplankton (Z), and detritus (D) components; counterflows of oxygen are not shown.

Figure 2 - Global distribution of oxygen (O_2) concentration in $mmol\ m^{-3}$ at 400, 900, and 1400 m (rows) for CanESM5-CanOE, CanESM5, the mean for other (non-CanESM) CMIP6 models, and World Ocean Atlas [20132018](#) (WOA[20132018](#)) observations (columns). Difference from the observation-based fields are shown in Supplementary Figure S3.

Figure 3 - Latitude-depth distribution (surface to 1750 m) of zonal mean oxygen concentration (O_2), oxygen concentration at saturation ($O_2(sat)$), and apparent oxygen utilization (AOU) in $mmol\ m^{-3}$ for CanESM5-CanOE, CanESM5, the mean for other CMIP6 models, and observations (WOA[20132018](#)). Note different colour scales for different rows. Difference from the observation-based fields are shown in Supplementary Figure S3.

Figure 4 - Taylor diagrams (Taylor, 2001) comparing modelled and observed distributions of oxygen at specific depths from 100 to 3500 m. Angle from the vertical indicates spatial pattern correlation. Distance from the origin indicates ratio of standard deviation in modelled vs. observed (WOA[20132018](#)) fields. Red dots represent CanESM5-CanOE, blue dots CanESM5, small grey dots other CMIP6 models, and large grey dots the model ensemble mean for all CMIP6 models except CanESM5 and CanESM5-CanOE.

Figure 5 - Total volume of ocean with oxygen (O_2) concentration less than (a) $6\ mmol\ m^{-3}$ (mean for last 30 years of the historical experiment) and (b) $60\ mmol\ m^{-3}$. Observation are from WOA[20132018](#).

Figure 6 - Global distribution of aragonite saturation (Ω_A) at 400, 900, and 3500 m for CanESM5-CanOE, CanESM5, the mean for other CMIP6 models, and observations (GLODAPv2 + WOA[20132018](#)). Note different colour scales for different depths. Difference from the observation-based fields are shown in Supplementary Figure S3.

Figure 7 - Latitude-depth distribution of zonal mean (surface to 1150 m) aragonite saturation state (Ω_A), calcite saturation state (Ω_C), and carbonate ion concentration ($[CO_3^{--}]$) in $mmol\ m^{-3}$ for CanESM5-CanOE, CanESM5, the mean for other CMIP6 models, and observations (GLODAPv2 + WOA[20132018](#)). Difference from the observation-based fields are shown in Supplementary Figure S3.

Figure 8 - Taylor diagrams comparing modelled and observed distributions of DIC at specific depths from 100 to 3500 m. Observations are from GLODAPv2 (Lauvset et al., 2016). Red dots represent CanESM5-CanOE, blue dots CanESM5, magenta dots CanESM2, small grey dots other CMIP6 models, and large grey dots the model ensemble mean for all CMIP6 models except CanESM5 and CanESM5-CanOE.

Figure 9 - Taylor diagrams comparing modelled and observed (GLODAPv2 + WOA[20132018](#)) distributions of Ω_A at specific depths from 100 to 3500 m. Symbol colours as in Figure 8.

Figure 10 - Climatological seasonal cycle of surface nitrate concentration averaged for selected ocean regions. Thick red line represents CanESM5-CanOE, thick blue line CanESM5, thick black line observations (WOA20132018), thin grey lines individual CMIP6 models, and thick grey line the model ensemble mean (excluding CanESM5 and CanESM5-CanOE). Regional boundaries are given in Supplementary Table S4S5 and Supplementary Figure S5.

Figure 11 - Climatological seasonal cycle of zonal mean surface nitrate concentration for a selection of CMIP6 models, a model ensemble mean (MEM) excluding CanESM5 and CanESM5-CanOE, and an observation-based data product (WOA20132018). [An alternate version showing only for \(a\) all latitudes and \(b\) latitudes <20° is given in Supplementary Figure S6.](#)

Figure 12 - Global distribution of dissolved iron (dFe) concentration (\log_{10} of concentration in nmol m^{-3}) at the ocean surface for CanESM5-CanOE and other CMIP6 models that published this field. Concentrations exceeding 1000 nmol m^{-3} are masked white. [CanESM5 is not included because it does not have prognostic iron.](#)

Figure 13 - Global mean depth profiles of dissolved iron concentration for CanESM5-CanOE and other CMIP6 models that published this field. GFDL-CM4 is excluded because it has very high concentrations ($>2000 \text{ nmol m}^{-3}$) near the surface. Thick red line represents CanESM5-CanOE, thin grey lines individual CMIP6 models, and the thick grey line the model ensemble mean (excluding CanESM5-CanOE and GFDL-CM4).

Figure 14 - Mean surface nitrate (NO_3) vs. dissolved iron (dFe) concentrations in different oceans, including the major high nutrient / low chlorophyll (HNLC) regions. CanESM5-CanOE is shown as a red dot and other CMIP5 models as grey dots (CanESM5 is not included because it does not have iron). Observed NO_3 is shown as a vertical black line as there are no observational estimates of dFe concentration. [For GFDL-CM4, nitrate is estimated as phosphate x 16.](#) Region definitions are given in Supplementary Table S4S5 and Supplementary Figure S5.

Figure 15 - Surface nitrate (NO_3) concentrations along the Pacific equator (mean from 2°S - 2°N) during the upwelling season (June-October) for CanESM5-CanOE (red), CanESM5 (blue), and WOA20132018 observations (black).

Figure 16 - Annual mean surface ocean concentration of large and small phytoplankton and zooplankton in CanESM5-CanOE (red) and of phytoplankton and zooplankton in CanESM5 (blue) for the representative ocean regions shown in Figure 14. Observational estimates (black) are for phytoplankton biomass calculated from satellite ocean colour estimates of surface chlorophyll (SeaWiFS/MODIS; Tesdal et al. 2016), assuming a carbon-to-chlorophyll ratio of 50 g/g . Region definitions are given in Supplementary Table S54 and Supplementary Figure S5.

Figure 17 - Mean annual cycle of surface chlorophyll for the representative ocean regions shown in Figures 14 and 16. CanESM5-CanOE large and small phytoplankton concentrations are shown separately and combined (red) along with CanESM5 (blue) and observational estimates (black). Region definitions are shown in Supplementary Table S54 and Supplementary Figure S5.

Figure 18 - Climatological surface particulate organic carbon (POC) vs. chlorophyll for CanESM5-CanOE (red) and observations (black). Data are for all ocean grid points ($2 \times 2^\circ$ uniform global grid) for all months of the year where observational data are available. Model POC is offset 17 mg m^{-3} for illustrative purposes. [Observed chlorophyll concentrations \$> 1 \text{ mg m}^{-3}\$ are excluded as they largely represent coastal areas poorly resolved by coarse resolution global ocean models.](#)

Figure 19 - (a) Global total export production (epc100) in PgC y^{-1} (b) and zonal mean export production in $\text{molC m}^{-2} \text{ y}^{-1}$ according to selected CMIP6 models (mean for 1985-2014 of historical experiment). Thick red line represents CanESM5-CanOE, thick blue line CanESM5, thin grey lines individual CMIP6 models, and thick grey line the model ensemble mean (excluding CanESM5 and CanESM5-CanOE).

Figure 20 - Cumulative ocean uptake of carbon dioxide (CO_2) as anthropogenic dissolved inorganic carbon (AnthDIC) in PgC over the course of the historical experiment (1850-2014). Data are shown as successive five-year means. CMIP6 mean (thick grey line) indicates ensemble mean for CMIP6 models (thin grey lines) excluding CanESM5 (blue) and CanESM5-CanOE (red). An observation-based estimate of $145 \pm 20 \text{ PgC}$ (Friedlingstein et al., 2020) is shown for nominal year 2014 (black).

Figure 21 - Change in export production (epc100) over the course of the historical experiment (1850-2014), normalized to the 1850-1900 mean. Data are shown as successive five-year means. Thick red line represents CanESM5-CanOE, thick blue line CanESM5, thin grey lines other CMIP6 models, and thick grey line the ensemble mean of non-CanESM models.

Figure 22 - (a) Change in total ocean volume with oxygen (O_2) concentration less than (a) 6 mmol m^{-3} and (b) 60 mmol m^{-3} over the course of the historical experiment (1850-2014), normalized to the 1850-1870 mean. Data are shown as successive five-year means. Thick red line represents CanESM5-CanOE, thick blue line CanESM5, and thin grey lines other CMIP6 models..

Dissolved iron model comparison to observations

As there is no gridded global data product for dissolved iron (dFe) we present here some comparisons with individual bottle samples from the GEOTRACES Intermediate Data Product 2017 (Schlitzer et al., 2018), the MBARI data compilation (www3.mbari.org/chemsensor/Data/), and the Pacific data set compiled by PICES WG22 (meetings.pices.int/members/working-groups/disbanded/wg22). The MBARI data include both profile (the "Global Iron Data") and surface transect ("MBARI SOLAS") data (the SOLAS data also include some profiles but are primarily underway surface measurements). The GEOTRACES data are primarily profile data (393 profiles total, only ~10% of 7519 data are <50 m). Most of the MBARI data are also in the PICES data set; these were preprocessed to remove redundant data. Data from the underway surface transects were excluded to avoid overweighting these regions due to autocorrelation, leaving a total of 3575 data points. Concentrations > 2.5 nM, which comprise 1.3% of GEOTRACES data and 3.3% of PICES/MBARI data, were excluded from the model/data comparisons below, [except for the individual GA-02 profiles](#).

Evaluating the CanOE model beyond what has been discussed in the main text identified several key points, most of which have already been made to some degree. CanESM5-CanOE compares favourably with other CMIP6 models but is quite biased towards a 'nutrient-type' rather than 'scavenged-type' profile (Figures [S4S9b](#), c, e-hg). [In](#) CanOE rates of Fe scavenging are very high above 0.6 nM dFe and very low below this concentration, resulting in an almost constant deep water concentration of 0.6 nM. The collected data (of which there are >10000 vs only a few hundred in 1997) show that the basic hypothesis articulated by Johnson et al. (1997) still holds: deep-water concentrations are generally close to 0.6 nM, although much higher concentrations are sometimes observed at depths of thousands of metres (Figure [S4S9b](#), see e.g. Resing et al., 2014). High concentrations are also sometimes observed in near-surface waters (Figure [S4S9b](#)) and [CanESM5-CanOE](#) is among the models least able to reproduce these. [CanESM5-CanOE](#) consistently overestimates the lowest observed concentrations and underestimates the higher ones (Figure [S4S9d](#)). One might argue that other models do little better in a statistical sense. However, in several models the deviations from the 1:1 line are less systematic than in [CanESM5-CanOE](#); the residuals may be larger but they are more homogeneous. [This comparison also largely confirms the results of Séférian et al. \(2020, their Figure 5\), although only two of the four models shown here were included in their analysis. CNRM-ESM2-1 shows a capacity to simulate the full range of dFe concentrations, as was the case in Séférian et al., although in no case is the spatial pattern correlation very large \(in Séférian et al., CNRM-ESM2-1 was the second highest at 0.21\). Nonetheless, this analysis indicates that Therefore purely statistical comparisons as in Figures S4S9e-g can be misleading. CanESM5-CanOE shows fairly good skill by these metrics but has systematic biases.](#) These biases can clearly be attributed to the rather simplistic scavenging model employed, and will be addressed in future versions.

[We made direct comparisons of our modelled dissolved iron concentrations with GEOTRACES transect data for GA-02 in the Atlantic \(e.g., Middag et al. 2015\), which was the most spatially extensive transect available \(Figure S9a\). We show depth profiles from 47°S to 47°N. Mostly this confirms what we already knew from the other analyses presented: our model has a very low scavenging rate below 0.6 nM and a very high rate above, so that deep water concentrations are quite uniform and near-surface concentrations are biased low in high-deposition regions like the northern tropical Atlantic. For the most part, the model reproduces the observed concentrations quite well, given these known biases. What we learn from including this additional analysis is \(a\) the model is biased high in the Antarctic Bottom Water \(Middag et al. 2015 give an excellent presentation of the location and biogeochemical properties of this water mass\), and \(b\) the seasonal biological drawdown in the mid-latitude North Atlantic is weak. The former is probably due mainly to the low scavenging rate at](#)

concentrations <0.6 nM, although it may also indicate a high bias in surface waters of the source region (see section 3.3). The latter is probably related to the generally low rate of export production (Figure 19) and the weak North Atlantic spring/summer bloom (Figures 16 and 17). Model annual mean data are shown, but seasonal minima are not much less, compared to the strong summer drawdown in the observations.

Figure S4S9a – Global distribution of dissolved iron (dFe) measurements in the GEOTRACES (black/green) and PICES/MBARI (blue) data compilations. GEOTRACES Pacific data north of 25°S are indicated in green. Blue dots outside the Pacific are MBARI data. [Large symbols indicate stations along GA-02 that are compared in Figure S9h.](#)

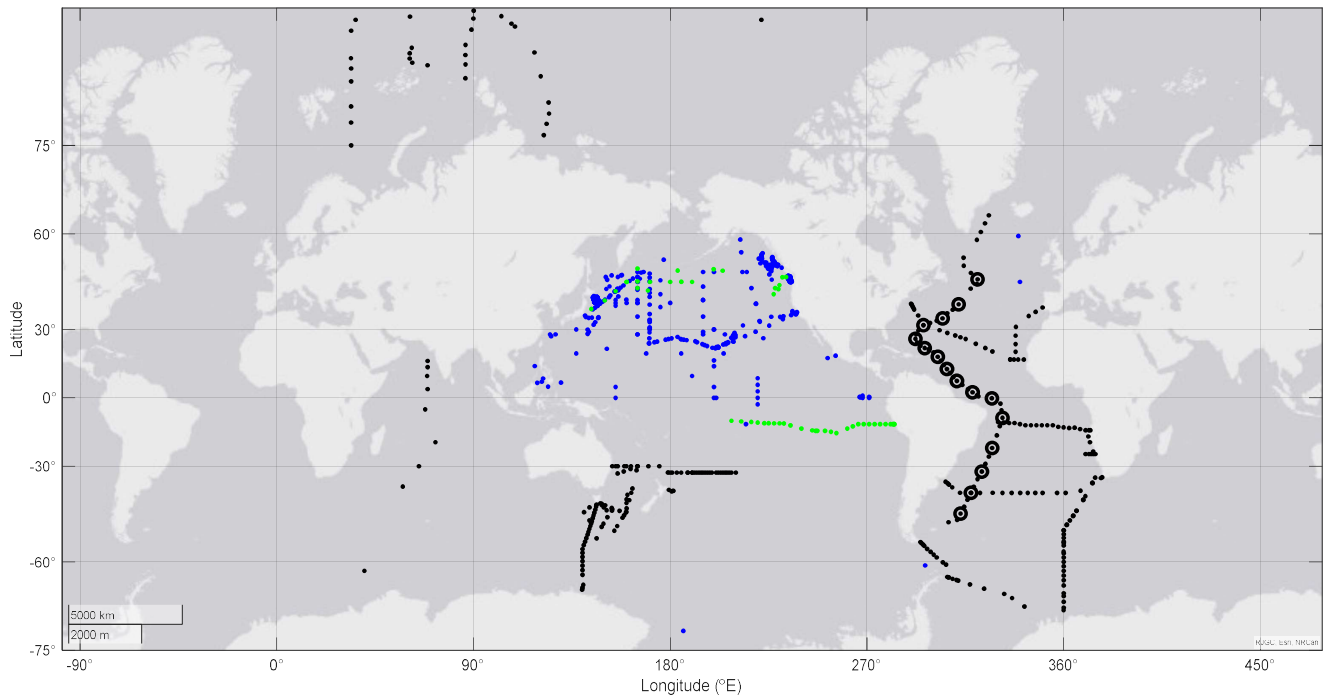

Figure S4S9b - All observations of dissolved iron (dFe) concentration (<2 nM) plotted against sampling depth. GEOTRACES data are in black and PICES/MBARI data are blue. Model data are global mean profiles of annual mean data as in Figure 13 in the main text.

Figure S4S9c - Mean of observations of dissolved iron (dFe) concentration (<2 nM) for various depth strata, including both GEOTRACES and PICES/MBARI data. Means of all data available in that depth range; spatial coverage is very incomplete and inconsistent among the depth strata. Averaging layers are 50 m (0-1000 m), 100 m (1000-3000 m) or 300 m (>3000 m) thick. Model data are global mean profiles of annual mean data as in Figure 13 in the main text.

Figure S4S9d - Modelled and observed mean dissolved iron (dFe) concentrations (excluding those >2.5 nM) in the upper 50 m at locations where a depth profile was taken (N=1122). Observed data are means of all measurements made at depths <50 m within a given profile. Model data are climatological surface values for the month in which the observed data were collected (red: CanESM5-CanOE; black CNRM-ESM2-1; blue: GFDL-CM4; magenta: MPI-ESM1-2-LR). Selection of models is somewhat arbitrary but includes the models that show the highest overall skill according to the metrics shown in Figures S4S9e-g. Thin lines are linear regressions for individual models; thick black line is 1:1.

Figure S4S9e - Root mean square error and correlation coefficient for surface dissolved iron data (upper 50 m mean with maximum of 2.5 nM, as in Figure S4S9d) for CMIP6 models for which seasonal data were available.

Figure S4S9f - As S4S9e but for the Pacific only (north of 25°S).

Figure S4S9g - As S4S9e but excluding the Pacific north of 25°S.

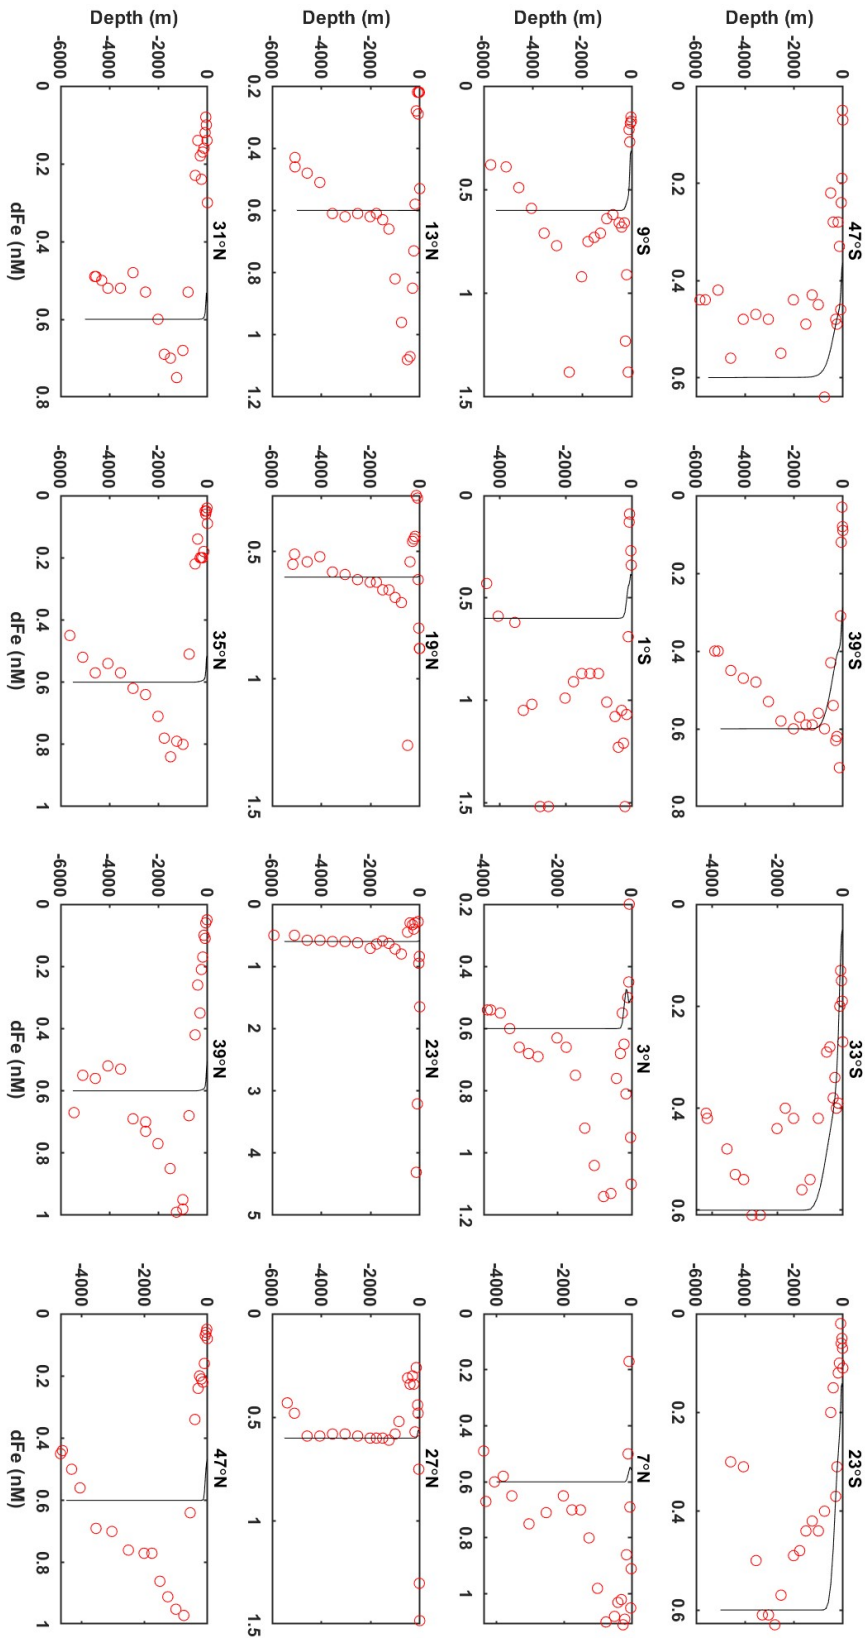

Figure S9h - Depth profiles for modelled and observed dissolved iron along the GA-02 transect of the Atlantic Ocean. Station locations are shown in Figure S9a (every third station, sorted by latitude). Model data are annual means.
