19 **Abstract.** The ocean biogeochemistry components of two new versions of the Canadian Earth
20 System Model are presented and compared to observations and other models. CanESM5
21 employs the same ocean biology model as CanESM2 whereas CanESM5-CanOE (“Canadian
22 Ocean Ecosystem model”) is a new, more complex model developed for CMIP6, with multiple
23 food chains, flexible phytoplankton elemental ratios, and a prognostic iron cycle. This new
24 model is described in detail and the outputs (distributions of major tracers such as oxygen,
25 dissolved inorganic carbon, and alkalinity, the iron and nitrogen cycles, plankton biomass, and
26 historical trends in CO₂ uptake and export production) compared to CanESM5 and CanESM2, as
27 well as to observations and other CMIP6 models. Both CanESM5 models show gains in skill
28 relative to CanESM2, which are attributed primarily to improvements in ocean circulation.
29 CanESM5-CanOE shows improved skill relative to CanESM5 for most major tracers at most
30 depths. CanESM5-CanOE includes a prognostic iron cycle, and maintains high nutrient / low
31 chlorophyll conditions in the expected regions (in CanESM2 and CanESM5, iron limitation is
32 specified as a temporally static ‘mask’). Surface nitrate concentrations are biased low in the
33 subarctic Pacific and equatorial Pacific, and high in the Southern Ocean, in both CanESM5 and
34 CanESM5-CanOE. Export production in CanESM5-CanOE is among the lowest for CMIP6
35 models; in CanESM5 it is among the highest, but shows the most rapid decline after about 1980.
36 CanESM5-CanOE shows some ability to simulate aspects of plankton community structure that a
37 single-species model can not (e.g., seasonal dominance of large cells), but is biased towards low
38 concentrations of zooplankton and detritus relative to phytoplankton. Cumulative ocean uptake
39 of anthropogenic carbon dioxide through 2014 is lower in both CanESM5-CanOE (122 PgC) and
40 CanESM5 (132 PgC) than in observation-based estimates (145 PgC) or the model ensemble
41 mean (144 PgC)..

42

43 1. Introduction

44

45 The Canadian Centre for Climate Modelling and Analysis has been developing coupled models
46 with an interactive carbon cycle for more than a decade (Christian et al., 2010; Arora et al.,
47 2011). The Canadian Earth System Model version 5 (CanESM5, Swart et al., 2019a) is an
48 updated version of CanESM2 (Arora et al., 2011), with a new ocean model based on the Nucleus
49 for European Modelling of the Ocean (NEMO) system version 3.4. The ocean biogeochemistry
50 modules were developed in-house. CanESM5 uses the same ocean biology model as CanESM1
51 (Christian et al., 2010) and CanESM2 (Arora et al., 2011), the Canadian Model of Ocean Carbon
52 (CMOC; Zahariev et al., 2008). An additional model was developed for CMIP6, called the
53 Canadian Ocean Ecosystem model (CanOE). The biological components of CanOE are of
54 substantially greater complexity than CMOC, including multiple food chains, flexible
55 phytoplankton elemental ratios, and a prognostic iron (Fe) cycle. The two coupled models are
56 known as CanESM5 and CanESM5-CanOE, respectively.

57

58 The reasons for developing both models are, firstly, to evaluate the effect of changes in ocean
59 circulation between CanESM2 and CanESM5 on ocean biogeochemistry by running the new
60 climate model with the same ocean biogeochemistry, and secondly because CanOE is
61 substantially more expensive computationally (19 tracers vs 7, so the total computation time to
62 integrate the ocean model with biogeochemistry is approximately double). Most CMIP6
63 experiments were run with CanESM5 only, as ocean biogeochemistry is not central to their
64 purpose. Additional tracers requested by the Ocean Model Intercomparison Project -
65 Biogeochemistry (OMIP-BGC) including abiotic and natural dissolved inorganic carbon (DIC),

66 DI^{14}C , CFCs and SF_6 (see Orr et al., 2017) were run only in CanESM5. The CMIP6 experiments
67 published for CanESM5-CanOE are listed in Supplementary Table S1.

68
69 CMOC is a nutrient-phytoplankton-zooplankton-detritus (NPZD) model with highly
70 parameterized representations of phytoplankton Fe limitation, dinitrogen (N_2) fixation and
71 denitrification, and calcification and calcite dissolution (Zahariev et al., 2008; Supplementary
72 Figure S1). CanESM1 and CanESM2 did not include oxygen; CanESM5 includes oxygen as a
73 purely 'downstream' tracer that does not affect other biogeochemical processes. In CanESM5-
74 CanOE, denitrification is prognostic and dependent on the concentration of oxygen. Among the
75 less satisfactory aspects of CMOC biogeochemistry are, firstly, that Fe limitation is specified as a
76 static 'mask' that does not change with climate (it is calculated from the present-day
77 climatological distribution of nitrate, based on the assumption that regions without iron
78 limitation will have complete drawdown of surface nitrate at some point in the year), and
79 secondly, that denitrification is parameterized so that nitrogen (N) is conserved within each
80 vertical column, i.e., collocated with N_2 fixation in tropical and subtropical open-ocean regions
81 (Zahariev et al., 2008; Riche and Christian, 2018). This latter simplification produced excessive
82 accumulations of nitrate in Eastern Boundary Current (EBC) regions where most denitrification
83 occurs. CMOC also has a tendency to produce rather stark extremes of high and low primary and
84 export production (Zahariev et al., 2008), a well-known problem of NPZD models (Armstrong,
85 1994; Friedrichs et al., 2007). Our intent in developing CanOE was to alleviate, or at least
86 reduce, these biases, by including multiple food chains, a prognostic Fe cycle, and prognostic
87 denitrification. Dinitrogen fixation is still parameterized, but the CanOE parameterization
88 includes Fe (but not P) limitation, whereas in CMOC N_2 fixation tends to grow without bound in

89 a warming ocean as CMOC does not include P or Fe limitation (Riche and Christian, 2018).

90

91 In this paper we present a detailed model description for CanOE and an evaluation of both
92 CanESM5 and CanESM5-CanOE relative to observational data products and other available
93 models. CMOC has been well described previously (Zahariev et al., 2008) and the details are not
94 reiterated here. In some cases, CanESM2 results are also shown to illustrate which differences in
95 the model solutions arise largely from the evolution of the physical climate model, and which are
96 specifically associated with different representations of biogeochemistry. An overall evaluation
97 of the CanESM5 climate including the physical ocean is given in Swart et al. (2019a). Here, we
98 focus on biogeochemical variables, and have evaluated model performance in three main areas:
99 (1) the distribution of major tracers like oxygen, DIC and alkalinity, and the resulting saturation
100 state for CaCO_3 minerals, (2) the iron cycle and its interaction with the nitrogen cycle, and (3)
101 plankton community structure and the concentration and export of particulates. We first address
102 the major chemical species that are common to both models (and almost all other Earth System
103 Models) to determine whether a more complex biology model measurably improves skill, and
104 whether the updated circulation model improves skill relative to CanESM2. Then we examine
105 the areas where our two models differ: the presence of a prognostic iron cycle and multiple food
106 chains in CanOE. More specifically, does CanESM5-CanOE reproduce the geographic
107 distribution of High-Nutrient, Low-Chlorophyll (HNLC) regions? Does the large phytoplankton /
108 large zooplankton food chain become dominant under nutrient-rich conditions, and how does
109 having multiple detrital size classes affect particle flux and remineralization length scale?
110 Following this model evaluation, we present historical trends in ocean anthropogenic CO_2
111 uptake, export production, and total volume of low-oxygen waters over the historical (1850-

112 2014) experiment. Possible future changes under Shared Socioeconomic Pathway experiments
113 will be addressed in subsequent publications.

114

115 **2. Model Description**

116

117 CanESM5 (Swart et al., 2019a) is an updated version of CanESM2 (Arora et al., 2011), with an
118 entirely new ocean. The atmosphere model has the same T63 horizontal resolution, and contains
119 some important improvements in atmospheric physics (Swart et al., 2019a). The land surface
120 (Canadian Land Surface Scheme) and terrestrial carbon cycle (Canadian Terrestrial Ecosystem
121 Model) models are substantially the same as in CanESM2 with minor modifications as described
122 by Arora et al. (2020). The CanESM5 ocean is based on the NEMO modelling system version
123 3.4, with a horizontal resolution of 1° , telescoping to $1/3^\circ$ in the tropics, and 45 vertical levels
124 ranging in thickness from ~ 6 m near the surface to ~ 250 m in the deep ocean (Swart et al.,
125 2019a). All physical climate model components are the same in CanESM5 and CanESM5-
126 CanOE. There are no feedbacks between biology and the physical ocean model, so the physical
127 climate of CanESM5 and CanESM5-CanOE is identical in experiments with prescribed
128 atmospheric CO_2 concentration.

129

130 The NEMO system is a publicly available archive of codes based on the OPA (Océan
131 PArallelisé) ocean model (Madec and Imbard, 1996; Guilyardi and Madec, 1997) and the
132 Tracers in Ocean Paradigm (TOP) module for tracer advection and mixing. Our ocean
133 biogeochemistry modules are built within TOP, using NEMO v3.4.1, but have also been
134 implemented in NEMO 3.6 for regional downscaling applications (Holdsworth et al., 2021).

135
136 Carbon chemistry is based on the Best Practices Guide (Dickson et al., 2007) and the OMIP-
137 BGC data request (Orr et al., 2017) and are identical in CanESM5 and CanESM5-CanOE. All
138 calculations are done on the total scale and the recommended formulae for the equilibrium
139 constants are employed. The carbon chemistry solver was run for a fixed number of iterations
140 (ten in the surface layer, and five in the subsurface layers in CanESM5-CanOE). CanESM5 does
141 not solve the carbon chemistry equations in the subsurface layers. OMIP-BGC formulations for
142 CO₂ and O₂ solubility and gas exchange are employed. It is important to note here that the
143 carbon chemistry and gas exchange formulations used in CanESM2 (and other CMIP5 models)
144 are slightly different than those used in CMIP6. However, this difference is of little functional
145 significance, i.e., it will have a negligible impact on the distribution of [CO₃²⁻] compared to the
146 differences in DIC and alkalinity distribution. The initialization fields for nitrate, DIC and
147 alkalinity were also different in CanESM2. This will affect the total ocean inventory of DIC but
148 not the spatial distribution if the model is well equilibrated.

149
150 The CanOE biology model is based on the cellular regulation model of Geider et al. (1998).
151 There are two phytoplankton size classes, and each group has four state variables: C, N, Fe and
152 chlorophyll. Photosynthesis is decoupled from cell production and photosynthetic rate is a
153 function of the cell's internal N and Fe quotas. Each functional group has a specified minimum
154 and maximum N quota and Fe quota, and nutrient uptake ceases when the maximal cell quota is
155 reached. Chlorophyll synthesis is a function of N uptake and increases at low irradiance. There
156 are also two size classes each of zooplankton and detritus. Small zooplankton graze on small

157 phytoplankton, while large zooplankton graze on both large phytoplankton and small
 158 zooplankton. Small detritus sinks at 2 m d^{-1} and large detritus at 30
 159 m d^{-1} (in CanESM5 there is a single detrital pool with a sinking rate of 8 m d^{-1}). Model
 160 parameters and their values are listed in Table 1. A schematic of the model is shown in Figure 1.

161

162 **2.1 Photosynthesis and Phytoplankton Growth**

163

164 For simplicity and clarity, the equations are shown here for a single phytoplankton species, and
 165 do not differ structurally for small and large phytoplankton. Some parameter values differ for the
 166 two phytoplankton groups; all parameter values are listed in Table 1.

167

168 Temperature dependence of photosynthetic activity is expressed by the Arrhenius equation

$$169 \quad T_f = \exp\left(-\frac{E_{ap}}{R}\left(\frac{1}{T} - \frac{1}{T_{ref}}\right)\right) \quad (1)$$

170 where E_{ap} is an enzyme activation energy that corresponds approximately to that of RuBisCo (cf.
 171 Raven and Geider 1988), R is the gas constant ($8.314 \text{ J mol}^{-1} \text{ K}^{-1}$), and temperature T and
 172 reference temperature T_{ref} are in Kelvin. Maximal rates of nutrient (either N or Fe, but
 173 generically referred to here with the superscript X) uptake are given by

$$174 \quad V_{max}^X = V_{ref}^X T_f \left(\frac{Q_{max}^X - Q^X}{Q_{max}^X - Q_{min}^X}\right)^{0.05} \quad (2)$$

175 where V_{max}^X is the maximal uptake rate in mg of nutrient X per mg of cell C, X can represent N
 176 or Fe, Q is the nutrient cell quota and Q_{min} and Q_{max} its minimum and maximum values, and V_{ref}^X
 177 is a (specified) basal rate at $T=T_{ref}$ and $Q=Q_{min}$. These maximum rates are then reduced according
 178 to the ambient nutrient concentration, i.e.

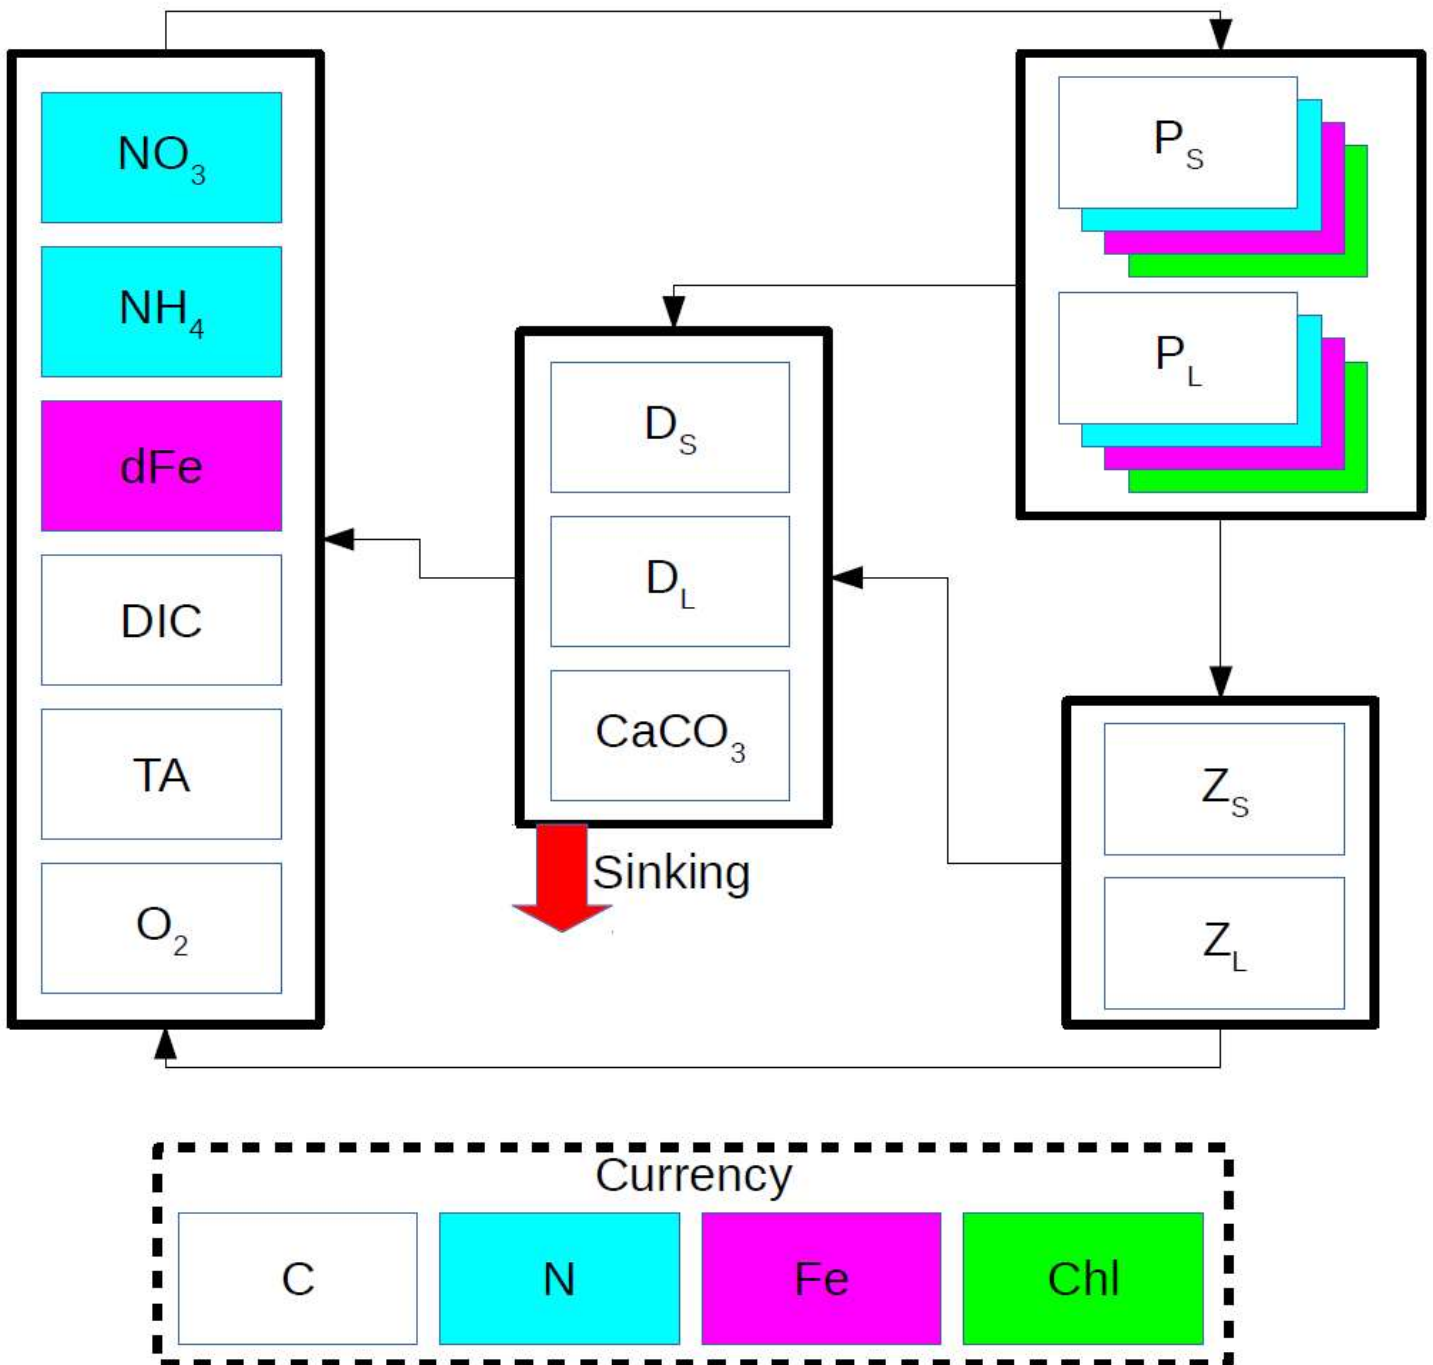

Figure 1 - Schematic of the CanOE biology model. Model currencies including chlorophyll (Chl) are indicated by coloured boxes except oxygen (O_2) and carbonate (CaCO_3). Arrows indicate flows of carbon (C), nitrogen (N) and iron (Fe) between compartments containing small (S) and large (L) phytoplankton (P), zooplankton (Z), and detritus (D) components; counterflows of oxygen are not shown.

Table 1 – Ecosystem model parameters.

Symbol	Description	Unit	
T_{ref}	Reference temperature	K	298.15
E_{ap}	Activation energy for photosynthesis	kJ mol^{-1}	37.4
$Q_{\text{mins}}^{\text{N}}$	Small phytoplankton minimum N quota	g N g C^{-1}	0.04
$Q_{\text{maxs}}^{\text{N}}$	Small phytoplankton maximum N quota	g N g C^{-1}	0.172
$Q_{\text{minl}}^{\text{N}}$	Large phytoplankton minimum N quota	g N g C^{-1}	0.04
$Q_{\text{maxl}}^{\text{N}}$	Large phytoplankton maximum N quota	g N g C^{-1}	0.172
$Q_{\text{mins}}^{\text{Fe}}$	Small phytoplankton minimum Fe quota	$\mu\text{g Fe g C}^{-1}$	4.65
$Q_{\text{maxs}}^{\text{Fe}}$	Small phytoplankton maximum Fe quota	$\mu\text{g Fe g C}^{-1}$	93.
$Q_{\text{minl}}^{\text{Fe}}$	Large phytoplankton minimum Fe quota	$\mu\text{g Fe g C}^{-1}$	6.5
$Q_{\text{maxl}}^{\text{Fe}}$	Large phytoplankton maximum Fe quota	$\mu\text{g Fe g C}^{-1}$	70.
$V_{\text{ref}}^{\text{N}}$	Reference rate of N uptake	$\text{g N g C}^{-1} \text{d}^{-1}$	0.6
$V_{\text{ref}}^{\text{Fe}}$	Reference rate of Fe uptake	$\mu\text{g Fe g C}^{-1} \text{d}^{-1}$	79.
$P_{\text{ref}}^{\text{C}}$	Reference rate of photosynthesis	$\text{g C g C}^{-1} \text{d}^{-1}$	3
k_{XU}	Rate coefficient for exudation	d^{-1}	1.7
k_{dgr}	Rate coefficient for chlorophyll degradation	d^{-1}	0.02
ζ	Respiratory cost of biosynthesis	g C g N^{-1}	2
α_{chl}	Initial slope of P-E curve	$\text{g C g CHL}^{-1} \text{h}^{-1} (\mu\text{mol m}^{-2} \text{s}^{-1})^{-1}$	1.08
$\Theta_{\text{max}}^{\text{N}}$	Maximum chlorophyll-nitrogen ratio	g g^{-1}	0.18
K_{NiS}	Half-saturation for small phytoplankton nitrate uptake	$\text{mmol}^{-1} \text{m}^3$	0.1
K_{NaS}	Half-saturation for small phytoplankton ammonium uptake	$\text{mmol}^{-1} \text{m}^3$	0.05
K_{FeS}	Half-saturation for small phytoplankton iron uptake	$\text{nmol}^{-1} \text{m}^3$	100
K_{NiL}	Half-saturation for large phytoplankton nitrate uptake	$\text{mmol}^{-1} \text{m}^3$	1.0
K_{NaL}	Half-saturation for large phytoplankton ammonium uptake	$\text{mmol}^{-1} \text{m}^3$	0.05
K_{FeL}	Half-saturation for large phytoplankton iron uptake	$\text{nmol}^{-1} \text{m}^3$	200
$m_{1\text{S}}$	Small phytoplankton/zooplankton mortality rate (linear)	d^{-1}	0.05
$m_{2\text{S}}$	Small phytoplankton/zooplankton mortality coefficient	$(\text{mmol C m}^{-3})^{-1} \text{d}^{-1}$	0.06
$m_{1\text{L}}$	Large phytoplankton/zooplankton mortality rate (linear)	d^{-1}	0.1

m_{2L}	Large phytoplankton/zooplankton mortality coefficient	$(\text{mmol C m}^{-3})^{-1} \text{ d}^{-1}$	0.06
X_{minp}	Minimum phytoplankton concentration for linear mortality	mmol C m^{-3}	0.01
a_L	Large zooplankton grazing parameter	$(\text{mmol C m}^{-3})^{-1}$	0.25
G_{L0}	Large zooplankton maximum grazing rate	d^{-1}	0.85
a_S	Small zooplankton grazing parameter	$(\text{mmol C m}^{-3})^{-1}$	0.25
G_{S0}	Small zooplankton maximum grazing rate	d^{-1}	1.7
λ	Assimilation efficiency	n.d.	0.8
r_{Zs}	Microzooplankton specific respiration rate at T_{ref}	d^{-1}	0.3
r_{Zl}	Mesozooplankton specific respiration rate at T_{ref}	d^{-1}	0.1
r_1	Small detritus remineralization rate at T_{ref}	d^{-1}	0.25
r_2	Large detritus remineralization rate at T_{ref}	d^{-1}	0.25
E_{ar}	Activation energy for detritus remineralization	kJ mol^{-1}	54.0
w_s	Small detritus sinking speed	m d^{-1}	2.
w_l	Large detritus sinking speed	m d^{-1}	30.
w_{Ca}	CaCO_3 sinking speed	m d^{-1}	20.
P_{Ca}	CaCO_3 production as fraction of mortality	$\text{mol CaCO}_3 \text{ molC}^{-1}$	0.05
k_{Ca}	CaCO_3 dissolution rate	d^{-1}	0.0074
$S_{\text{Fe}1}$	Dissolved iron scavenging loss rate ($\text{Fe} \leq L_{\text{Fe}}$)	d^{-1}	0.001
$S_{\text{Fe}2}$	Dissolved iron scavenging loss rate ($\text{Fe} > L_{\text{Fe}}$)	d^{-1}	2.5
L_{Fe}	Ligand concentration	nmol Fe m^{-3}	600.
P_{Fe}	POC-dependence parameter for Fe scavenging	$(\text{mmolC m}^{-3})^{-1}$	0.66
$k_{\text{NH}4\text{ox}}$	Nitrification rate constant	d^{-1}	0.05
K_E	Half-saturation for irradiance inhibition of nitrification	W m^{-2}	1.
k_{dnf}	Light and nutrient saturated rate of N_2 fixation at 30°C	$\text{mmol N m}^{-3} \text{ d}^{-1}$	0.0225
a	Initial slope for irradiance-dependence of N_2 fixation	$(\text{W m}^{-2})^{-1}$	0.02
K_{Fe}	Half-saturation for Fe dependence of N_2 fixation	nmol Fe m^{-3}	100.
$K_{\text{NO}3}$	Half-saturation for DIN inhibition of N_2 fixation	mmol m^{-3}	0.1
O_{mxd}	O_2 concentration threshold for denitrification	mmol m^{-3}	6.
A_f	Anammox fraction of N loss to denitrification	n.d.	0.25

182 $V^N = V_{max}^N (L_{NH4} + (1 - L_{NH4})L_{NO3})$ (3a)

183 where $L_{NH4} = \frac{N_a}{K_{NaX} + N_a}$ and $L_{NO3} = \frac{N_i}{K_{NiX} + N_i}$, with N_i and N_a indicating nitrate and ammonium

184 respectively, and

185 $V^{Fe} = V_{max}^{Fe} \left(\frac{Fe}{K_{FeX} + Fe} \right)$ (3b)

186 where X indicates large or small phytoplankton (Table 1). The maximal carbon-based growth

187 rate is given by

188 $P_{max}^C = P_{ref}^C T_f \min \left\{ \frac{Q^N - Q_{min}^N}{Q_{max}^N - Q_{min}^N}, \frac{Q^{Fe} - Q_{min}^{Fe}}{Q_{max}^{Fe} - Q_{min}^{Fe}} \right\}$ (4)

189 where P_{ref}^C is the rate at the reference temperature T_{ref} under nutrient-replete conditions

190 ($Q=Q_{max}$). The light-limited growth rate is then given by

191 $P_{phot}^C = P_{max}^C \left(1 - e^{-\alpha_{chl} E \theta_C / P_{max}^C} \right)$ (5)

192 where E is irradiance and θ_C is the chlorophyll-to-carbon ratio. The rate of chlorophyll synthesis

193 is

194 $\rho_{chl} = \theta_{max}^N \frac{P_{phot}^C}{E \alpha_{chl} \theta}$ (6)

195 These rates are then used to define a set of state equations for phytoplankton carbon (C_p),

196 nitrogen (N_p), iron (Fe_p), and chlorophyll (M).

197 $\frac{dC_p}{dt} = (P_{phot}^C - \zeta V_N) C_p - (G + C_{XS}) - m_1 C_p - m_2 C_p^2 - k_{XU} C_{INTR}$ (7)

198 where ζ is the respiratory cost of biosynthesis, G is the grazing rate (equation 12), C_{XS} is the

199 excess (above the ratio in grazer biomass) carbon in grazing losses (see below equation 16a), m_1

200 and m_2 are coefficients for linear and quadratic nonspecific mortality terms, C_{INTR} is the

201 concentration of intracellular carbohydrate carbon in excess of biosynthetic requirements, and

202 k_{XU} is a rate coefficient for its exudation to the environment. The nonspecific mortality terms are
 203 set to 0 below $0.01 \text{ mmol C m}^{-3}$, to prevent biomass from being driven to excessively low levels
 204 in the high latitudes in winter; linear mortality terms can result in biomass declining to levels
 205 from which recovery would take much longer than the brief Arctic summer (Hayashida, 2018).
 206 The full equation for phytoplankton N, Fe and chlorophyll are

$$207 \quad \frac{dN_p}{dt} = \frac{V^N}{Q_N} - (G + m_1 C_p + m_2 C_p^2) R_{NC} - N_{XS} \quad (8)$$

$$208 \quad \frac{dFe_p}{dt} = \frac{V^{Fe}}{Q_{Fe}} - (G + m_1 C_p + m_2 C_p^2) R_{FeC} - Fe_{XS} \quad (9)$$

$$209 \quad \frac{dM}{dt} = \frac{\rho_{chl} V^N}{\theta_C} M - (G + m_1 C_p + m_2 C_p^2) \theta_C - k_{dgr} M \quad (10)$$

210 where k_{dgr} is a rate coefficient for nonspecific losses of chlorophyll e.g., by photooxidation, in
 211 addition to losses to grazing and other processes that also affect C_p , N_p , and Fe_p . N_{XS} and Fe_{XS} are
 212 remineralization of "excess" (relative to grazer or detritus ratios) N or Fe and are defined below
 213 (equation 16).

214

215 **2.2 Grazing and Food Web Interactions**

216

217 Grazing rate depends on the phytoplankton carbon concentration, which most closely represents
 218 the food concentration available to the grazer (Elser and Urabe 1999; Loladze et al. 2000).

219 Zooplankton biomass is also in carbon units. State equations for small and large zooplankton are

$$220 \quad \frac{dZ_s}{dt} = \lambda G_s - (R + G_Z + m_{1s} Z_s + m_{2s} Z_s^2) \quad (11a)$$

$$221 \quad \frac{dZ_L}{dt} = \lambda G_L - (R + m_{1L} Z_L + m_{2L} Z_L^2) \quad (11b)$$

222 where

223 $G_S = G_{S0}(1 - e^{-a_S C_{ps}})Z_S$ (12a)

224 $G_L = G_{L0}(1 - e^{-a_L(C_{pl}+Z_S)})Z_L$ (12b)

225 for small and large zooplankton respectively, G_Z is grazing of small zooplankton by large
 226 zooplankton, R is respiration, and m_1 and m_2 are nongrazing mortality rates. Large zooplankton
 227 grazing is divided into grazing on large phytoplankton and small zooplankton in proportion to
 228 the relative abundance of each

229 $G_P = G_L \frac{P_L}{P_L+Z_S}$ (13a)

230 $G_Z = G_L \frac{Z_S}{P_L+Z_S}$ (13b)

231 Zooplankton biomass loss to respiration is given by

232 $R = \max\{r_Z T_f Z - C_{XS}, 0\}$ (14)

233 and uses the same activation energy as photosynthesis. Respiration (R) is assumed to consume
 234 only carbon and not result in catabolism of existing biomass when “excess” carbon is available
 235 in the prey. In addition, conservation of mass must be maintained by recycling to the dissolved
 236 pool grazer consumption of elements in excess of biosynthetic requirements when grazer and
 237 prey elemental ratios differ. In the case where the nutrient quota (relative to carbon) exceeds the
 238 grazer fixed ratio, the excess nutrient is remineralized to the dissolved inorganic pool. In the case
 239 where the nutrient quota is less than the grazer ratio, the grazer intake is reduced to what can be
 240 supported by the least abundant nutrient (relative to the grazer biomass ratio) and excess carbon
 241 is remineralized. For the case of two nutrients (in this case N and Fe) it is necessary to define

242 $G' = G \min\left\{\frac{N_P}{C_P} R_{CN}, \frac{Fe_P}{C_P} R_{CFe}, 1\right\}$ (15)

243 where G is equal to G_S (equation 12a) for small zooplankton and G_P (equation 13a) for large
 244 zooplankton, and R_{XY} indicates the fixed ratio of element X to element Y in grazer biomass. The
 245 'excess' carbon available for respiration is

$$246 \quad C_{XS} = G' \left\{ \frac{C_P}{N_P} R_{NC} - 1, \frac{C_P}{Fe_P} R_{FeC} - 1, 0 \right\} \quad (16a)$$

247 and the excess nutrients remineralized to their inorganic pools are

$$248 \quad N_{XS} = G' \max \left\{ \frac{N_P}{C_P} - R_{NC}, 0 \right\} \varepsilon + G' \max \left\{ R_{NC} \left(\frac{N_P}{Fe_P} R_{FeN} - 1 \right), 0 \right\} (1 - \varepsilon) \quad (16b)$$

$$249 \quad Fe_{XS} = G' \max \left\{ \frac{Fe_P}{C_P} - R_{FeC}, 0 \right\} \varepsilon + G' \max \left\{ R_{FeC} \left(\frac{Fe_P}{N_P} R_{NFe} - 1 \right), 0 \right\} (1 - \varepsilon) \quad (16c)$$

250 where

$$251 \quad \varepsilon = \frac{\max\{C_{XS}, 0\}}{C_{XS} + \Delta}$$

252 is a switch to prevent double-counting in cases where one of the terms is redundant (the excess
 253 relative to the least abundant element is included in the other term), but would otherwise be
 254 nonzero (Δ is a constant equal to 10^{-15} , to prevent divide-by-zero). For three elements, there are
 255 $3! = 6$ possible cases: for N greater or less than $C_P R_{NC}$, Fe may be either in excess relative to
 256 both C and N, deficient relative to both, or in excess relative to one but not the other (Table 2).

257

258 Table 2 - Cases where the 'excess' terms are nonzero. These terms are always greater than or
 259 equal to zero, and always zero when the phytoplankton elemental ratio is equal to the grazer bio-
 260 mass ratio. A plus (+) sign indicates that a specific term is positive. N_1 and N_2 , Fe_1 and Fe_2 indi-
 261 cate the first and second terms in equations 16b and 16c. R_{NC} is the grazer N/C (Redfield) ratio.
 262

	Fe in excess relative to both C and N					Fe in excess relative to C or N but not both					Fe deficient relative to both C and N				
	C	N_1	N_2	Fe_1	Fe_2	C	N_1	N_2	Fe_1	Fe_2	C	N_1	N_2	Fe_1	Fe_2
$N/C > R_{NC}$		+		+			+		+		+		+		
$N/C < R_{NC}$	+				+	+				+	+		+		

263 2.3 Organic and Inorganic Pools

264

265 There are two pools of detritus with different sinking rates but the same fixed elemental ratios.

266 Detrital C/N/Fe ratios are the same as zooplankton, so zooplankton mortality or grazing of small

267 zooplankton by large zooplankton produce no 'excess'. Phytoplankton mortality, and defecation

268 by zooplankton grazing on phytoplankton, produces excess nutrient or excess C that needs to be

269 recycled into the inorganic pool in a similar fashion as outlined above for the assimilated fraction

270 of grazing on phytoplankton.

271 The conservation equations for detrital C are

$$272 \frac{dD_s}{dt} = m_1(C_{ps} + Z_s) + m_2(C_{ps}^2 + Z_s^2) - r_1 D_s T_g - w_s \frac{dD_s}{dz} \quad (17a)$$

$$273 \frac{dD_l}{dt} = m_1(C_{pl} + Z_l) + m_2(C_{pl}^2 + Z_l^2) - r_2 D_l T_g - w_l \frac{dD_l}{dz} \quad (17b)$$

274 where T_g is an Arrhenius function for temperature dependence of remineralization and w is the

275 sinking speed. The conservation equations for inorganic C, N, and Fe are

$$276 \frac{dC_i}{dt} = (\zeta V^N - P_{\text{phot}}^C) C_p + R + C_{\text{XS}} + (r_1 D_s + r_2 D_l) T_g \quad (18a)$$

$$277 \frac{dN_i}{dt} = -\frac{V^N}{Q^N} N_p \left(\frac{L_{\text{NO}_3}}{L_{\text{NO}_3} + L_{\text{NH}_4}} \right) + N_{\text{ox}} - N_{\text{dentr}} (1 - A_f) \quad (18b)$$

$$278 \frac{dN_a}{dt} = -\frac{V^N}{Q^N} N_p \left(\frac{L_{\text{NH}_4}}{L_{\text{NO}_3} + L_{\text{NH}_4}} \right) + \frac{R}{R_{\text{CN}}} + N_{\text{XS}} + (r_1 D_s + r_2 D_l) R_{\text{NC}} T_g - N_{\text{ox}} + N_{\text{dnf}} - N_{\text{dentr}} A_f \quad (18c)$$

$$279 \frac{d\text{Fe}}{dt} = \frac{V^{\text{Fe}}}{Q^{\text{Fe}}} \text{Fe}_p + \frac{R}{R_{\text{CFe}}} + \text{Fe}_{\text{XS}} + (r_1 D_s + r_2 D_l) R_{\text{FeC}} T_g \quad (18d)$$

280 where N_{ox} is microbial oxidation of ammonium to nitrate (nitrification), N_{dnf} and N_{dentr} are

281 sources and sinks associated with dinitrogen fixation and denitrification, and A_f is the ammonium

282 fraction of denitrification losses, associated with anaerobic ammonium oxidation ("anammox").

283 The oxygen equation is essentially the inverse of equation 18a, with additional terms for
 284 oxidation and reduction of N, i.e.,

$$285 \frac{dO_2}{dt} = -\frac{dC_i}{dt} + 2 \frac{V^N}{Q^N} N_p \left(\frac{L_{NO_3}}{L_{NO_3} + L_{NH_4}} \right) - 2N_{ox} \quad (19)$$

286 Nitrification is given by

$$287 N_{ox} = k_{NH_4ox} N_a \frac{K_E}{K_E + E(z)} \quad (20)$$

288 where $E(z)$ is the layer mean irradiance at depth z . Dinitrogen fixation is parameterized as an
 289 external input of ammonium dependent on light, temperature and Fe availability, and inhibited
 290 by high ambient concentrations of inorganic N,

$$291 N_{dnf} = k_{dnf} T_{dnf} (1 - e^{-aE}) \left(\frac{Fe}{K_{Fe} + Fe} \right) \left(\frac{K_{NO_3}}{K_{NO_3} + N_i + N_a} \right) \quad (21)$$

292 where $T_{dnf} = \max(0, 1.962(T_f - 0.773))$, i.e., a linear multiple of equation (1) that is 0 at $T < 20^\circ\text{C}$
 293 and unity at $T = 30^\circ\text{C}$. The temperature, iron and light limitation terms are based on PISCES
 294 (Aumont et al., 2015); the N-inhibition term is from CMOC (Zahariev et al., 2008) (CMOC
 295 implicitly combines nitrate and ammonium into a single inorganic N pool).

296

297 Denitrification is parameterized as a fraction of total remineralization that increases as a linear
 298 function of oxygen concentration for concentrations less than a threshold concentration O_{mxd}

$$299 N_{fixn} = 1 - \frac{\min(O_2, O_{mxd})}{O_{mxd}} \quad (22)$$

300 Remineralization is then divided among oxygen ($1 - N_{fixn}$), nitrate ($0.875N_{fixn}$), and ammonium
 301 ($0.125N_{fixn}$) assuming an average anammox contribution of 25% (Babbin et al., 2014). We use
 302 this average ratio of anammox to classical denitrification to partition fixed N losses between

303 NO_3^- and NH_4^+ ; the DIC sink and organic matter source associated with anammox are small and
304 are neglected here.

305

306 **2.4 Calcification, Calcite Dissolution, and Alkalinity**

307

308 In CanOE, calcification is represented by a prognostic detrital calcite pool with its own sinking
309 rate (distinct from that of organic detritus), and calcite burial or dissolution in the sediments
310 depends on the saturation state (100% burial when $\Omega_C \geq 1$, 100% dissolution when $\Omega_C < 1$).

311 Calcification is represented by a detrital calcium carbonate (CaCO_3) state variable, but no
312 explicit calcifier groups. Detrital CaCO_3 sinks in the same fashion as detrital particulate organic
313 carbon (POC), with a sinking rate independent of those for large and small organic detritus.

314 Calcite production is represented as a fixed fraction of detritus production from small
315 phytoplankton and small zooplankton mortality:

$$316 \frac{dCa}{dt} = m_1(C_{ps} + Z_s)P_{Ca} + m_2(C_{ps}^2 + Z_s^2)P_{Ca} - k_{Ca}Ca - w_{Ca} \frac{dCa}{dz} \quad (23)$$

317 Calcite dissolution occurs throughout the water column as a first order process (i.e., no
318 dependence on temperature or saturation state). Approximately 80% of calcite produced is
319 exported from the euphotic zone. In CanESM5-CanOE, burial in the sediments is represented as
320 a simple 'on/off' switch dependent on the calcite saturation state (zero when $\Omega_C < 1$ and 1 when
321 $\Omega_C \geq 1$). In CanESM5, calcification is parameterized by a temperature dependent “rain ratio”
322 (Zahariev et al., 2008) and 100% burial of calcite that reaches the seafloor is assumed. Calcite
323 burial in both models is balanced by an equivalent source of DIC and alkalinity at the ocean
324 surface (in the same vertical column) as a crude parameterization of fluvial sources.

325

326 For each mole of calcite production, two moles of alkalinity equivalent are lost from the
327 dissolved phase; the reverse occurs during calcite dissolution. There are additional sources and
328 sinks for alkalinity associated with phytoplankton nutrient (NH_4^+ , NO_3^-) uptake, organic matter
329 remineralization, nitrification, denitrification and dinitrogen fixation (Wolf-Gladrow et al., 2007,
330 see Supplementary Table S2). The anammox reaction does not in itself contribute to alkalinity
331 (Jetten et al., 2001), but there is a sink associated with ammonium oxidation to nitrite (the model
332 does not distinguish between nitrite and nitrate). Autotrophic production of organic matter by
333 anammox bacteria is a net source of alkalinity (Strous et al., 1998), but this source is extremely
334 small (~ 0.03 mol/molN) and is neglected here. Globally, the sources and sinks of alkalinity from
335 the N cycle offset each other such that there is no net gain or loss as long as the global fixed N
336 pool is conserved (see below Sect. 2.5). If dinitrogen fixation and denitrification are allowed to
337 vary freely, there will generally be a net gain or loss of fixed N and, therefore, of alkalinity.

338

339 **2.5 External Nutrient Sources and Sinks**

340

341 External sources and sinks consist of river inputs, aeolian deposition, biological N_2 fixation,
342 denitrification, mobilization of Fe from reducing sediments, loss of Fe to scavenging, and burial
343 of calcium carbonate in the sediments. There is no burial of organic matter; organic matter
344 reaching the seafloor is instantaneously remineralized. Aeolian deposition of Fe is calculated
345 from a climatology of mineral dust deposition generated from offline (atmosphere-only)
346 simulations with CanAM4 (von Salzen et al., 2013), with an Fe mass fraction of 5% and a
347 fractional solubility of 1.4% in the surface layer. Subsurface dissolution is parameterized based

348 on PISCESv2 (Aumont et al., 2015); the total dissolution is 6.35%, with 22% of soluble Fe input
 349 into the first vertical layer (see Supplementary material). Iron from reducing sediments is also
 350 based on PISCES, with a constant areal flux of 1000 nmol m⁻² d⁻¹ in the first model level,
 351 declining exponentially with increasing seafloor depth (i.e., assuming that shelf sediments are the
 352 strongest source and the sediments become progressively more oxygenated with increasing
 353 seafloor depth) with an e-folding length scale of about 600 m. Scavenging of dissolved iron is
 354 first-order with a high rate (2.5 d⁻¹) for concentrations in excess of 0.6 nM (Johnson et al., 1997).
 355 For concentrations below this threshold, the rate is much lower (0.001 d⁻¹) and is weighted by the
 356 concentration of organic detritus (Christian et al., 2002b), i.e.,

$$357 \frac{dFe}{dt} = -FeS_{Fe1} \min\{(D_S + D_L)P_{Fe}, 1\} \quad (24)$$

358 where Fe is the dissolved iron concentration, D_S and D_L are the small and large detritus
 359 concentrations, S_{Fe1} is the first-order scavenging rate in surface waters with abundant
 360 particulates, and P_{Fe} is an empirical parameter to determine the dependence on particle
 361 concentration (Table 1). The basis for this parameterization is that the rate of scavenging must
 362 depend not only on the concentration of iron but on the concentration of particles available for it
 363 to precipitate onto, and assumes that detrital POC is strongly positively correlated with total
 364 particulate matter. Scavenging is treated as irreversible, i.e., scavenged Fe is not tracked and
 365 does not reenter the dissolved phase.

366
 367 N₂ fixation and denitrification vary independently in CanOE, so the global total N pool can
 368 change. Conservation is imposed by adjusting the global total N pool according to the difference
 369 between the gain from N₂ fixation and the loss to denitrification. A slight adjustment is applied
 370 to the nitrate concentration at every grid point, while preserving the overall spatial structure of

371 the nitrate field. Adjustments are multiplicative rather than additive to avoid producing negative
372 concentrations. This adjustment does not maintain (to machine precision) a constant global N
373 inventory but is intended to minimize long term drift, keeping it much smaller than the free
374 surface error (see below). This adjustment is applied every 10 days and has a magnitude of
375 approximately 7×10^{-8} of the total N.

376
377 When the total fixed N adjustment is applied, one mole of alkalinity is added (removed) per mole
378 of N removed (added), to account for the alkalinity sources associated with N_2 fixation (creation
379 of new NH_4^+) and denitrification (removal of NO_3^-) (Wolf-Gladrow et al., 2007, see
380 Supplementary Table S2). As there is a 2 mol/molN sink associated with nitrification, this
381 formulation is globally conservative. As noted above, in CanOE $CaCO_3$ can dissolve or be buried
382 in the sediments depending on the calcite saturation state. DIC and alkalinity lost to burial are
383 reintroduced at the ocean surface, at the same grid point as burial occurs, providing a crude
384 parameterization of river inputs so that global conservation is maintained (fresh water runoff
385 contains no DIC or alkalinity). However, the OPA free surface formulation is inherently
386 imperfect with regard to tracer conservation. Drift in total ocean alkalinity and nitrogen over
387 time is on the order of 0.01% and 0.03% per thousand years, respectively.

388

389 **2.6 Ancillary data**

390

391 For first-order model validation we have relied largely on global gridded data products rather
392 than individual profile data. Global gridded data from World Ocean Atlas 2018 (WOA2018)
393 (Locarnini et al., 2018; Zweng et al., 2018; Garcia et al., 2018a; 2018b) were used for

394 temperature, salinity, and oxygen and nitrate concentration. DIC and alkalinity were taken from
395 the GLODAPv2.2016b gridded data product (Key et al., 2015; Lauvset et al., 2016). Offline
396 carbon chemistry calculations were done following the Best Practices Guide (Dickson et al.,
397 2007) and the OMIP-BGC protocols (Orr et al., 2017), and are identical to those used in the
398 models except that constant reference concentrations were used for phosphate (1 μM) and
399 silicate (10 μM).

400

401 There is no global gridded data product for Fe, but we have made use of the GEOTRACES
402 Intermediate Data Product 2017 (Schlitzer et al., 2018), and the data compilations from MBARI
403 (Johnson et al., 1997; 2003) and PICES Working Group 22 (Takeda et al., 2013). The latter two
404 are concentrated in the Pacific, while GEOTRACES is more global. The combined data sets
405 provide more than 10000 bottle samples from more than 1000 different locations (Supplementary
406 Figure S10a) (excluding some surface transect data that involve frequent sampling of closely
407 spaced locations along the ship track). More detail about model comparison to these data
408 compilations and the list of original references are given in the Supplementary information.

409

410 Satellite ocean colour estimates of surface chlorophyll were taken from the combined
411 SeaWiFS/MODIS climatology described by Tesdal et al. (2016). Climatological satellite POC
412 was downloaded from the NASA ocean colour web site and is based on the algorithm of
413 Stramski et al. (2008) using MODIS-Aqua data. This climatology differs slightly from the
414 chlorophyll one in terms of years included and sensors utilized, but as only climatological
415 concentrations are considered and each climatology covers ~ 15 years, these differences will have
416 negligible effect on the results presented. Satellite chlorophyll concentrations greater than 1 mg

417 m⁻³ were excluded as these are mostly associated with coastal regions not resolved by coarse-
418 resolution global ocean models.

419
420 CMIP6 model data were regridded by distance-weighted averaging using the Climate Data
421 Operators (<https://code.mpimet.mpg.de/projects/cdo/>) to a common grid (2x2°, 33 levels) to
422 facilitate ensemble averaging. The vertical levels used are those used in GLODAP and in earlier
423 (through 2009) versions of the World Ocean Atlas (e.g., Locarnini et al., 2010). For large scale
424 tracer distributions, using a 1° or 2° grid makes little difference (for example, the spatial pattern
425 correlation between CanESM5 and observed oxygen concentration at specific depths on a 1° or
426 2° grid differs by an average of 0.0011). The years 1986-2005 of the Historical experiment were
427 averaged into climatologies or annual means, for meaningful comparison with observation-based
428 data products. The CMIP6 Historical experiment runs from 1850-2014 with atmospheric CO₂
429 concentration (and other atmospheric forcings) based on historical observed values. A single
430 realization was used in each case (see Table S3); 20 year averages are used to minimize the
431 effect of internal variability (e.g., Arguez and Vose, 2011, see Table S4). Where time series are
432 shown, 5-year means are used.

433
434 Sampling among CMIP6 models was somewhat opportunistic, and the exact suite of models
435 varies among the analyses presented. When we conducted a search for a particular data field, we
436 included in the search parameters all models that published that field, and repeated the search at
437 least once for models that were unavailable the first time the search was executed. In some cases,
438 model ensemble means excluded all but one model from a particular ‘family’ (e.g., there are
439 three different MPI-ESM models for which ocean biogeochemistry fields were published), as the

440 solutions were found to be similar and would bias the ensemble mean towards their particular
441 climate. The models used are ACCESS-ESM1-5, CESM2, CESM2-WACCM, CNRM-ESM2-1,
442 GFDL-CM4, GFDL-ESM4, IPSL-CM6A-LR, MIROC-ES2L, MPI-ESM-1-2-HAM, MPI-
443 ESM1-2-LR, MPI-ESM1-2-HR, MRI-ESM2-0, NorESM2-LM, NorESM2-MM, and UKESM1-
444 0-LL. Details of which variables and realizations are used for which models are given in
445 Supplementary Table S3.

446

447 **3. Results**

448

449 We first describe the large-scale distribution of oxygen, DIC, alkalinity, and the saturation state
450 with respect to CaCO_3 that derives from these large-scale tracer distributions. Tracer
451 distributions result partly from ocean circulation and partly from biogeochemical processes. An
452 overall evaluation of the ocean circulation model is given in Swart et al. (2019a). Analyzing
453 CanESM5 and CanESM5-CanOE (with identical circulation) as well as CanESM2 where
454 possible (same biogeochemistry as CanESM5 but different circulation) allows us to separate the
455 effects of physical circulation and biogeochemistry on evolving model skill with respect to large-
456 scale tracer distributions. In subsequent sections we address the main areas where CanESM5 and
457 CanESM5-CanOE differ, such as the interaction of the iron and nitrogen cycles and plankton
458 community structure. Finally, we present some temporal trends over the course of the historical
459 experiment (1850-2014).

460

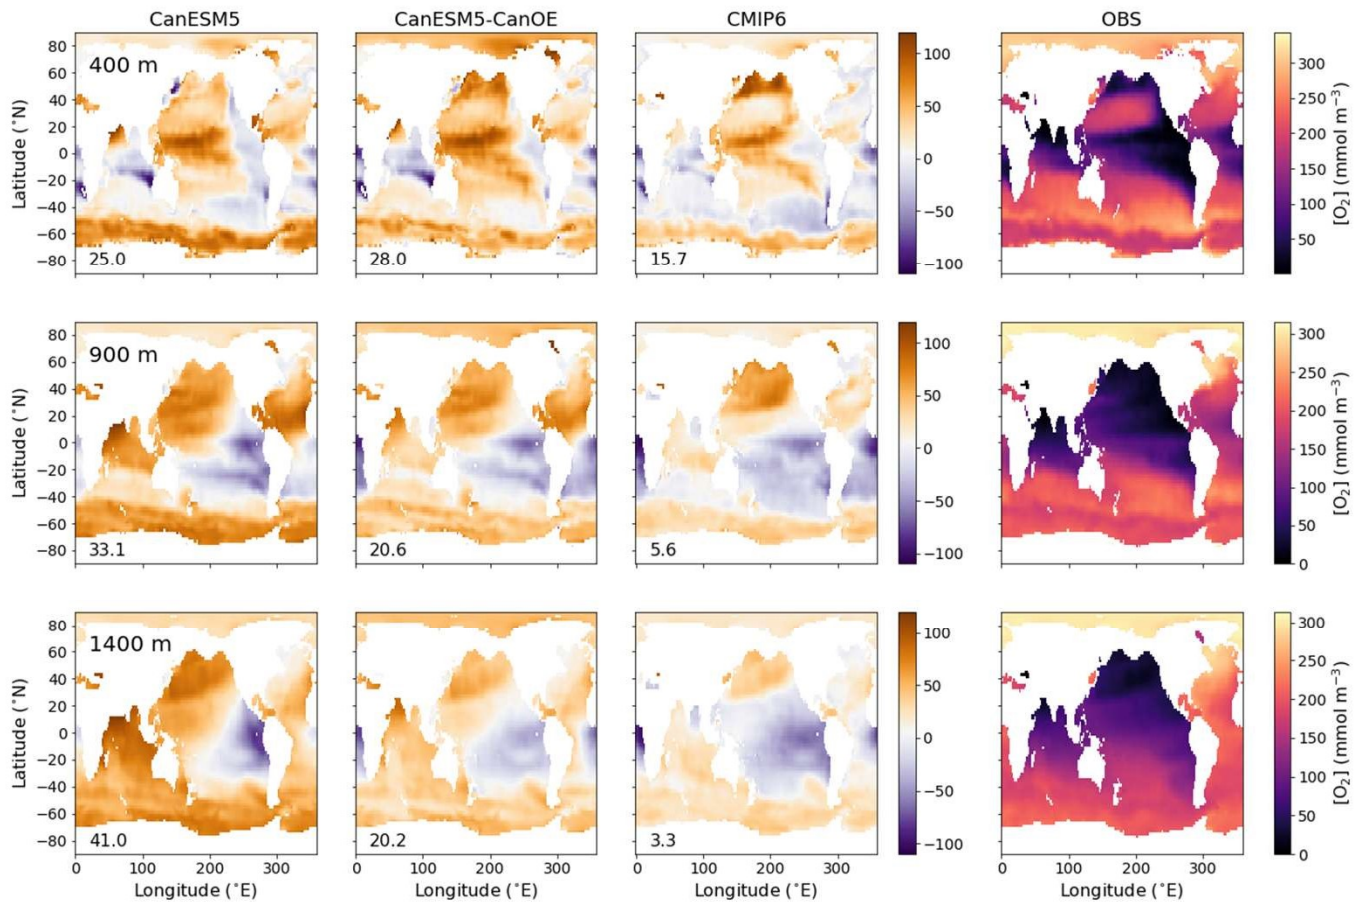

Figure 2 - Global distribution of oxygen (O_2) concentration in mmol m^{-3} at 400, 900, and 1400 m (rows). Observations (WOA2018) are in the right hand column; other columns show the difference from the observations of CanESM5-CanOE, CanESM5, and the mean for other CMIP6 models. Note different colour scales for different rows. Numbers at lower left are the mean model bias. Model concentrations are shown in Supplementary Figure S3.

462 3.1 Distribution of oxygen

463

464 The spatial distribution of oxygen concentration ($[O_2]$) at selected intermediate depths (400, 900,
465 and 1400 m) is shown in Figure 2 for gridded data from WOA2018 and differences from that
466 observational data product for CanESM5, CanESM5-CanOE, a model ensemble mean (MEM) of
467 CMIP6 models (excluding CanESM5 and CanESM5-CanOE). The depths were chosen to span
468 the depth range where low oxygen concentrations exist; these low-oxygen environments are of
469 substantial scientific and societal interest and are sensitive to model formulation. The major
470 features are consistent across the models. Both CanESM models as well as the MEM show
471 elevated oxygen concentrations relative to observations, particularly in the North Pacific, the
472 North Atlantic and the Southern Ocean. In the Indian Ocean, both CanESM models show high
473 oxygen concentrations in the Arabian Sea and deeper layers of the Bay of Bengal relative to
474 observations and the MEM; these biases are somewhat smaller in CanESM5-CanOE than in
475 CanESM5 (Figure 2).

476

477 The ocean's oxygen minimum zones (OMZs) are mostly located in the eastern Pacific Ocean, the
478 northern North Pacific, and the northern Indian Ocean; the spatial pattern changes with
479 increasing depth (Figure 2), but the OMZs are mostly located between 200 and 2000 m depth.
480 Biases in the EBC regions are depth and model specific. CanESM5 shows particularly strong
481 oxygen depletion at 1400 m in the eastern tropical Pacific. In the southeastern Atlantic, models
482 tend to be biased low at the shallower depths, and show somewhat more variation at greater
483 depths (Figure 2). Overall, $[O_2]$ biases tend to be positive over large areas of ocean with the
484 exception of some EBC regions, implying that models exaggerate the extent to which

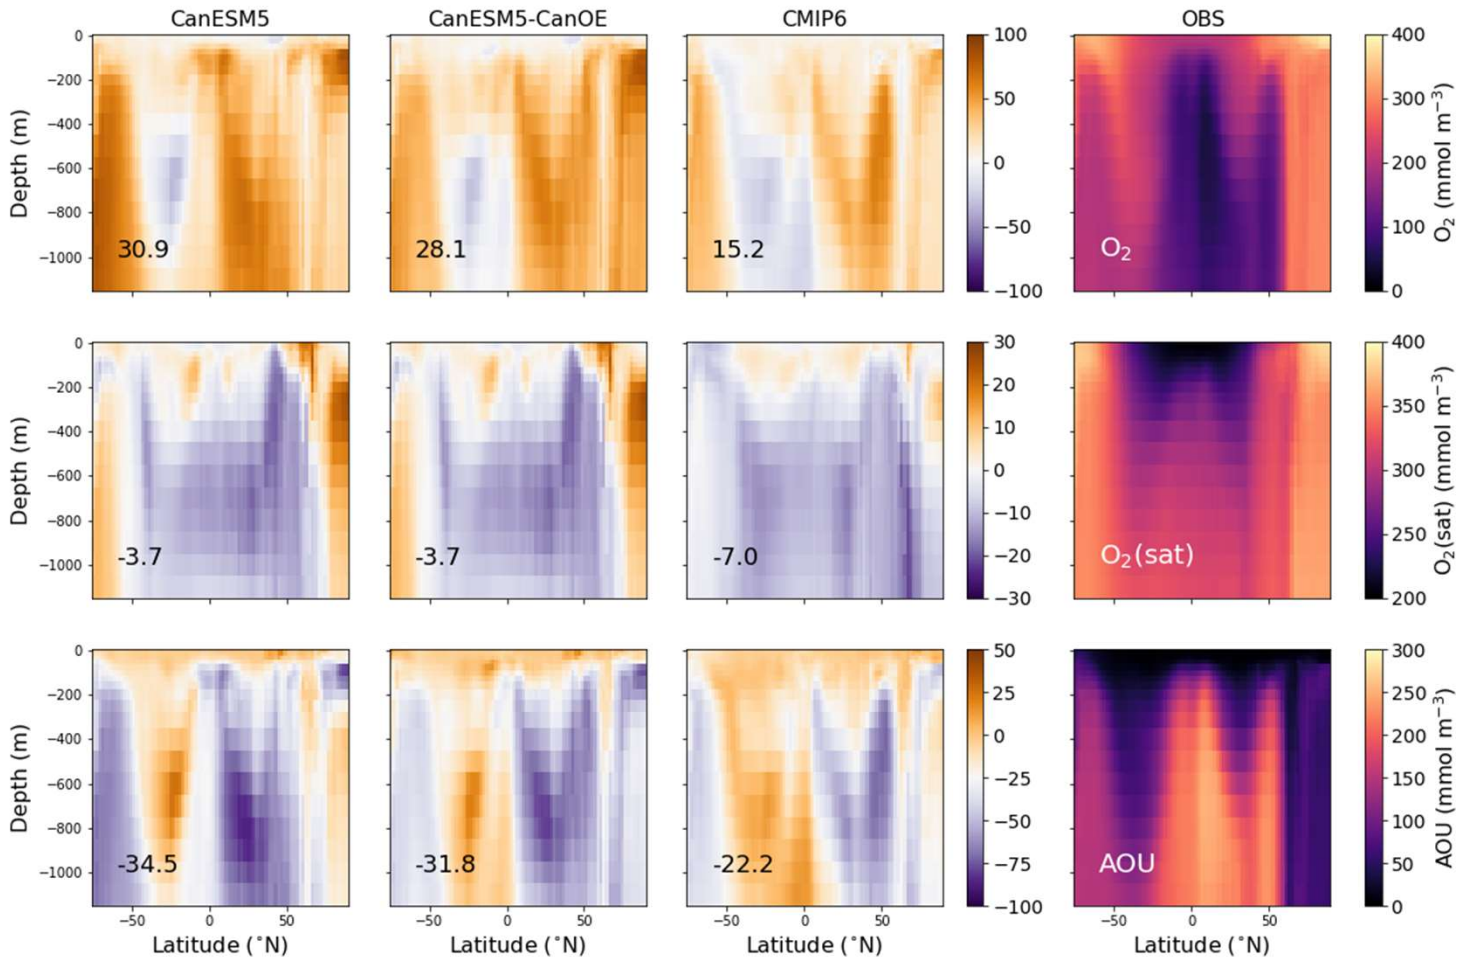

Figure 3 - Latitude-depth distribution (surface to 1750 m) of zonal mean oxygen concentration (O_2), oxygen concentration at saturation ($O_2(\text{sat})$), and apparent oxygen utilization (AOU) in mmol m^{-3} . Observations (WOA2018) are in the right hand column; other columns show the difference from the observations of CanESM5-CanOE, CanESM5, and the mean for other CMIP6 models. Note different colour scales for different rows. Numbers at lower left are the mean model bias. Model concentrations are shown in Supplementary Figure S3.

486 remineralization is concentrated in these regions. An alternate version of Figure 2 that shows the
487 modelled concentrations is given in Supplementary Figure S2.

488
489 The zonal mean oxygen concentration, saturation concentration, and apparent oxygen utilization
490 (AOU) are shown in Figure 3 for the same four cases. Again, the models generally show a
491 positive bias in $[O_2]$, particularly in high-latitude deep waters. The major ocean circulation
492 features are reproduced fairly well in all cases (e.g., weaker ventilation of low-latitude
493 subsurface waters, greater vertical extent of well-ventilated surface waters in the subtropics). The
494 saturation concentration (a function of temperature and salinity) generally shows relatively little
495 bias, implying that the bias in $[O_2]$ arises mainly from remineralization and/or ventilation. AOU
496 is lower than observed over much of the subsurface ocean. CanESM5 and CanESM5-CanOE
497 show a high bias over much of the Northern Hemisphere that reflects the high concentrations in
498 the North Pacific and North Atlantic (Figure 2). The overall trend of bias with latitude in
499 CanESM5 and CanESM5-CanOE is generally similar to the MEM, but the biases are larger. The
500 bias in CanESM5 is generally slightly larger than in CanESM5-CanOE, except in the Arctic
501 Ocean. Again, Supplementary Figure S2 includes a version of this plot that shows the modelled
502 concentration fields.

503
504 The skill of each model with respect to the distribution of O_2 at different depths is represented by
505 Taylor diagrams (Taylor, 2001) in Figure 4. These diagrams allow us to assess how well the
506 model reproduces the spatial distribution at a range of depths, because different physical and
507 biogeochemical processes determine the distribution in different depth ranges. All of the CMIP6
508 models that were shown as an ensemble mean in Figures 2 and 3 are shown individually. The

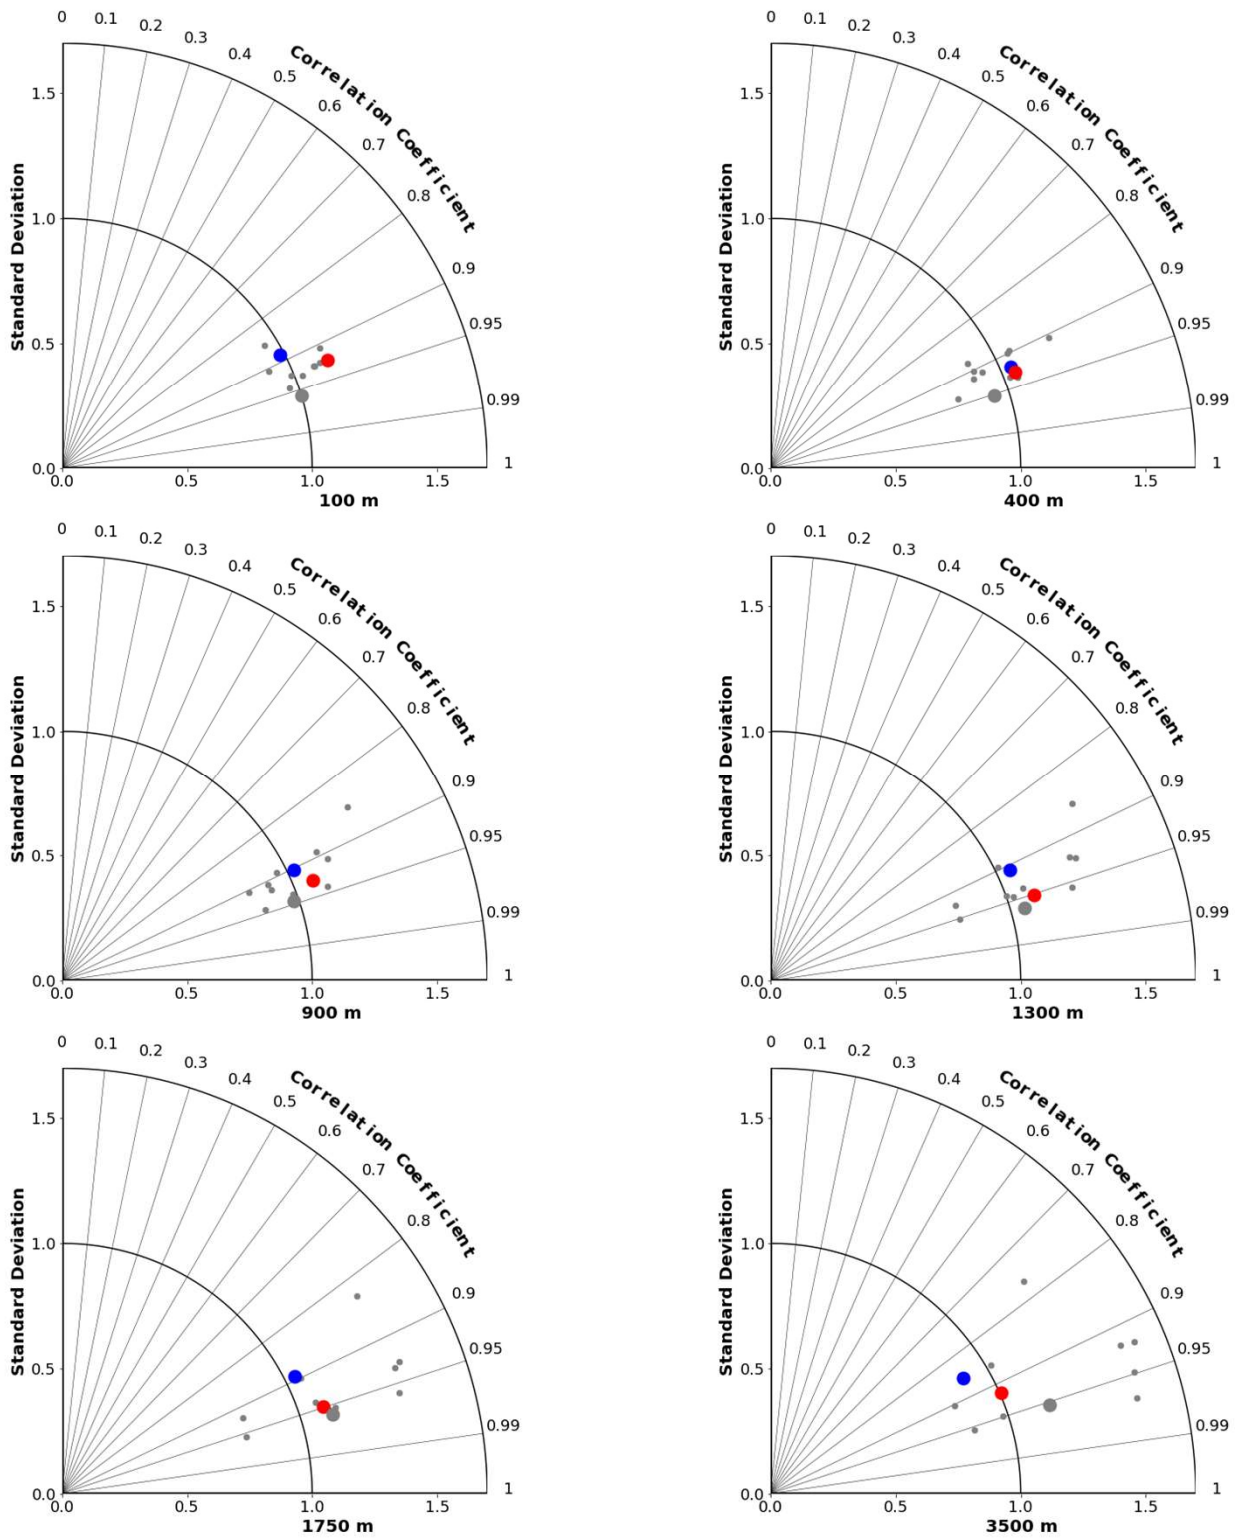

Figure 4 - Taylor diagrams (Taylor, 2001) comparing modelled and observed distributions of oxygen at specific depths from 100 to 3500 m. Angle from the vertical indicates spatial pattern correlation. Distance from the origin indicates ratio of standard deviation in modelled vs. observed (WOA2018) fields. Red dots represent CanESM5-CanOE, blue dots CanESM5, small grey dots other CMIP6 models, and large grey dots the model ensemble mean for all CMIP6 models except CanESM5 and CanESM5-CanOE.

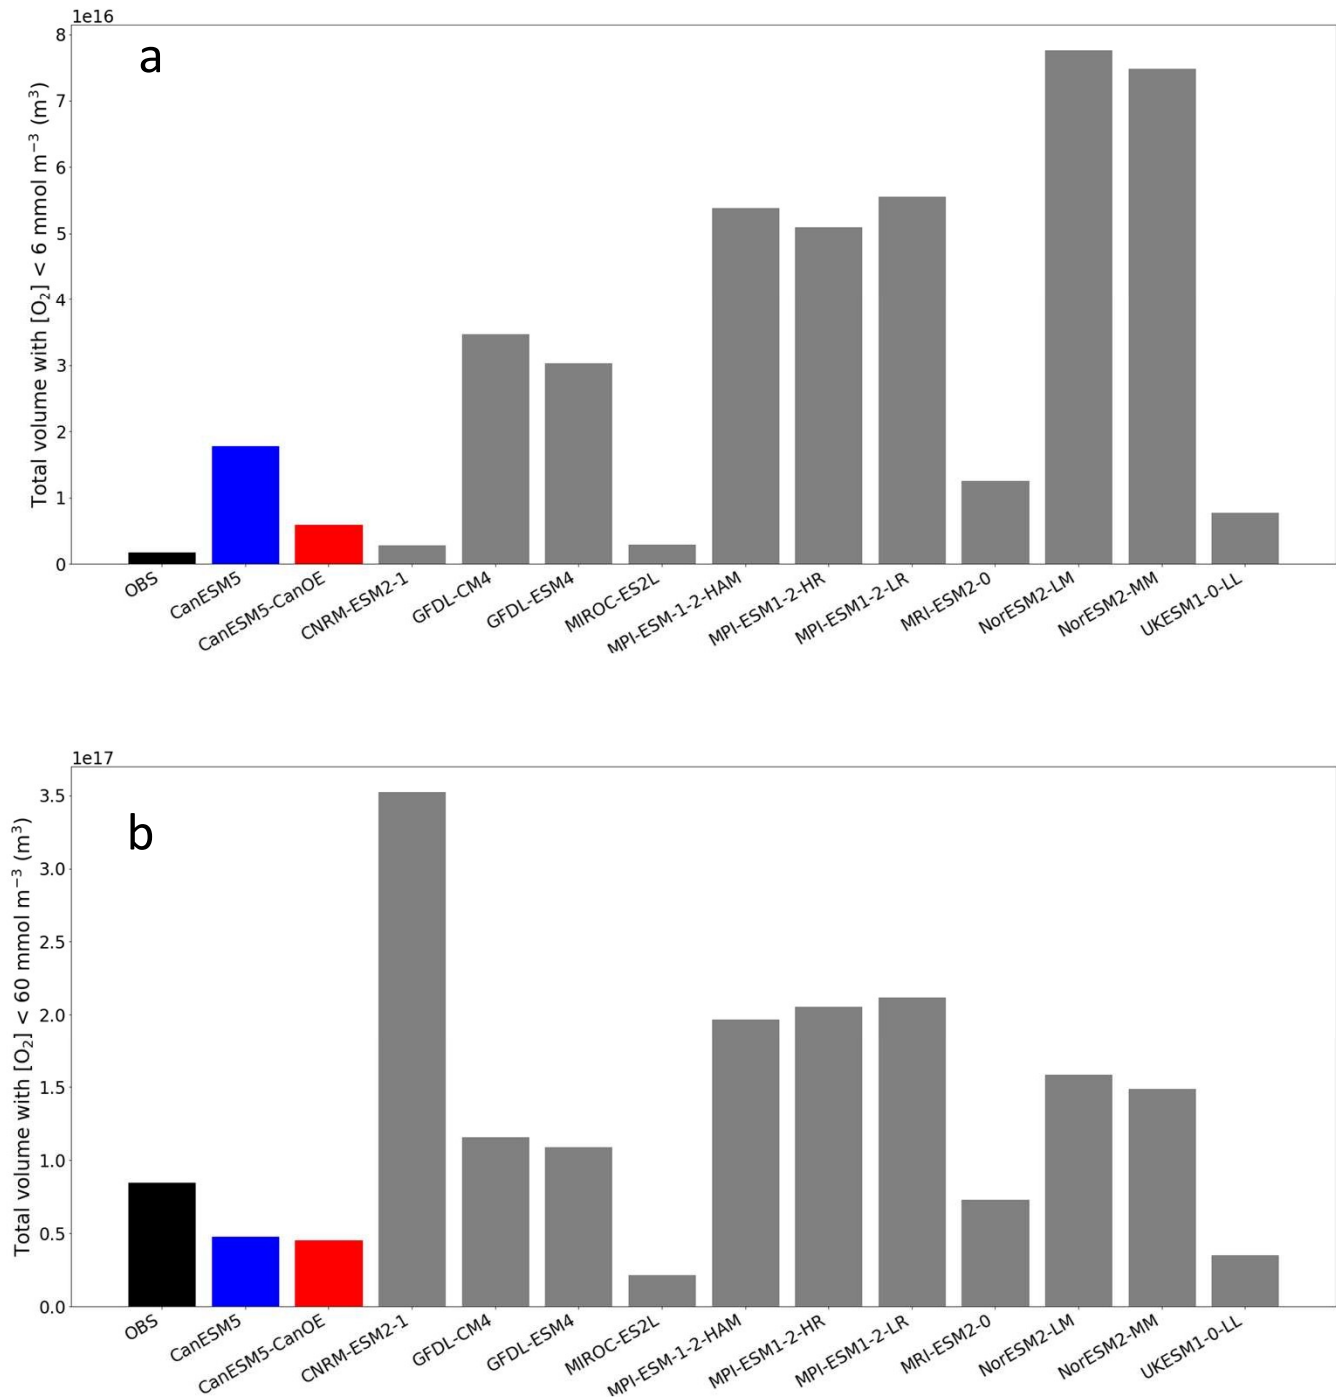

Figure 5 - Total volume of ocean with oxygen (O_2) concentration less than (a) 6 mmol m^{-3} (mean for last 30 years of the historical experiment) and (b) 60 mmol m^{-3} . Observation are from WOA2018.

511 large blue dots represent CanESM5, red CanESM5-CanOE, and grey the MEM; the smaller grey
512 dots represent the individual models. CanESM5-CanOE shows slightly higher pattern correlation
513 than CanESM5 at all depths. Both models compare favourably with the full suite of CMIP6
514 models, with $r > 0.85$ for CanESM5 and $r > 0.9$ for CanESM5-CanOE at all depths examined, and a
515 normalized standard deviation within $\pm 25\%$ of unity.

516

517 The total volume of ocean with $[O_2]$ less than 6 mmol m^{-3} (the threshold for denitrification
518 (Devol, 2008)) and 60 mmol m^{-3} (a commonly used index of hypoxia) is shown in Figure 5. The
519 total volume is highly variable among models (note, however, that there are several clusters of
520 related models with quite similar totals). CanESM5 and CanESM5-CanOE have among the
521 lowest total volumes (i.e., the interior ocean is relatively well ventilated) and are among the
522 nearest to the observed total. For $[O_2] < 60 \text{ mmol m}^{-3}$ the bias is, nonetheless, quite large (i.e., the
523 observed volume is underestimated by almost 50% in both models). The volume of water with
524 $[O_2]$ below the denitrification threshold is overestimated in both CanESM5 and CanESM5-
525 CanOE; CanESM5-CanOE has a much smaller total that is closer to the observed value. The bias
526 in the spatial pattern of hypoxia (not shown) is generally similar to the bias in dissolved oxygen
527 distribution (Figure 2). The low-oxygen regions are generally more concentrated in the eastern
528 tropical Pacific in the models than in observations, and the low-oxygen region in the northwest
529 Pacific is not well reproduced in CanESM models.

530

531 **3.2 Distribution of DIC, alkalinity, and $CaCO_3$ saturation**

532

533 The spatial distribution of aragonite saturation state (Ω_A) at selected depths is shown in Figure 6.

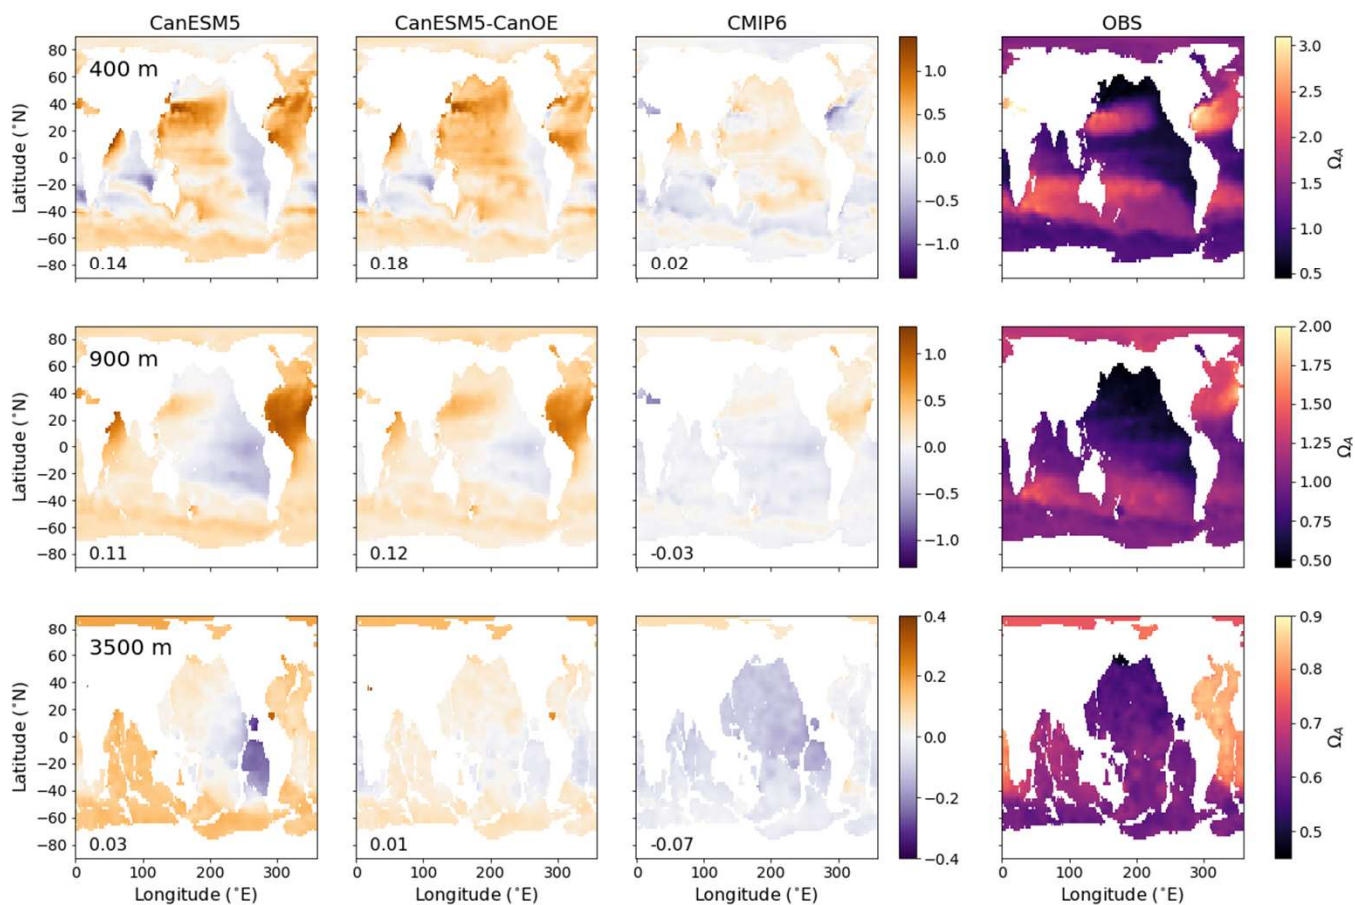

Figure 6 - Global distribution of aragonite saturation (Ω_A) at 400, 900, and 3500 m for CanESM5-CanOE, CanESM5, the mean for other CMIP6 models, and observations (GLODAPv2 + WOA2018). Note different colour scales for different depths. Numbers at lower left are the mean model bias. Difference from the observation-based fields are shown in Supplementary Figure S3.

535 The first two depths are the same as in Figure 2, but a much greater depth is also included, as the
536 length scale for CaCO_3 dissolution is greater than for organic matter remineralization. In this
537 case the observations are a combination of GLODAPv2 (Key et al., 2015; Lauvset et al., 2016)
538 for DIC and alkalinity, and WOA2018 for temperature and salinity. CanESM5 and CanESM5-
539 CanOE show an overall high saturation bias at the shallower depths, particularly in the North
540 Atlantic, with a low bias found mainly in the eastern Pacific. The low saturation bias in the
541 eastern tropical Pacific is substantially reduced in CanESM5-CanOE compared to CanESM5. On
542 the other hand CanESM5 generally does better than CanESM5-CanOE, or the MEM, at
543 reproducing the low saturation states in the northwestern Pacific and the Bering Sea. Both
544 CanESM models show a high saturation state bias in the North Atlantic and the well-ventilated
545 regions of the north Pacific subtropical gyre; these biases are slightly smaller in CanESM5-
546 CanOE. Maps of the calcite and aragonite saturation horizon ($\Omega=1$) depth are shown in
547 Supplementary Figure S3; these generally confirm the same biases noted in Figure 6.

548
549 Zonal mean distributions of aragonite saturation state (Ω_A), calcite saturation state (Ω_C), and
550 carbonate ion concentration ($[\text{CO}_3^{--}]$) and the differences of the models from the observations are
551 shown in Figure 7 (Supplementary Figure S2 includes versions of Figures 6 and 7 that show the
552 modelled fields). The models generally compare well with the observations in the representation
553 of the latitude/depth distribution of high and low saturation waters. CanESM5 has a high
554 saturation bias in low-latitude surface waters that is somewhat reduced in CanESM5-CanOE.
555 Both CanESM5 models show a high saturation bias in Northern Hemisphere intermediate (e.g.,
556 200-1000 m) depth waters that is larger than in the MEM. This is primarily a result of low Ω in
557 the North Atlantic Ocean (Figure 6).

Figure 7 - Latitude-depth distribution of zonal mean (surface to 1150 m) aragonite saturation state (Ω_A), calcite saturation state (Ω_C), and carbonate ion concentration ($[\text{CO}_3^{2-}]$) in mmol m^{-3} for CanESM5-CanOE, CanESM5, the mean for other CMIP6 models, and observations (GLODAPv2 + WOA2018). Numbers at lower left are the mean model bias. Difference from the observation-based fields are shown in Supplementary Figure S3.

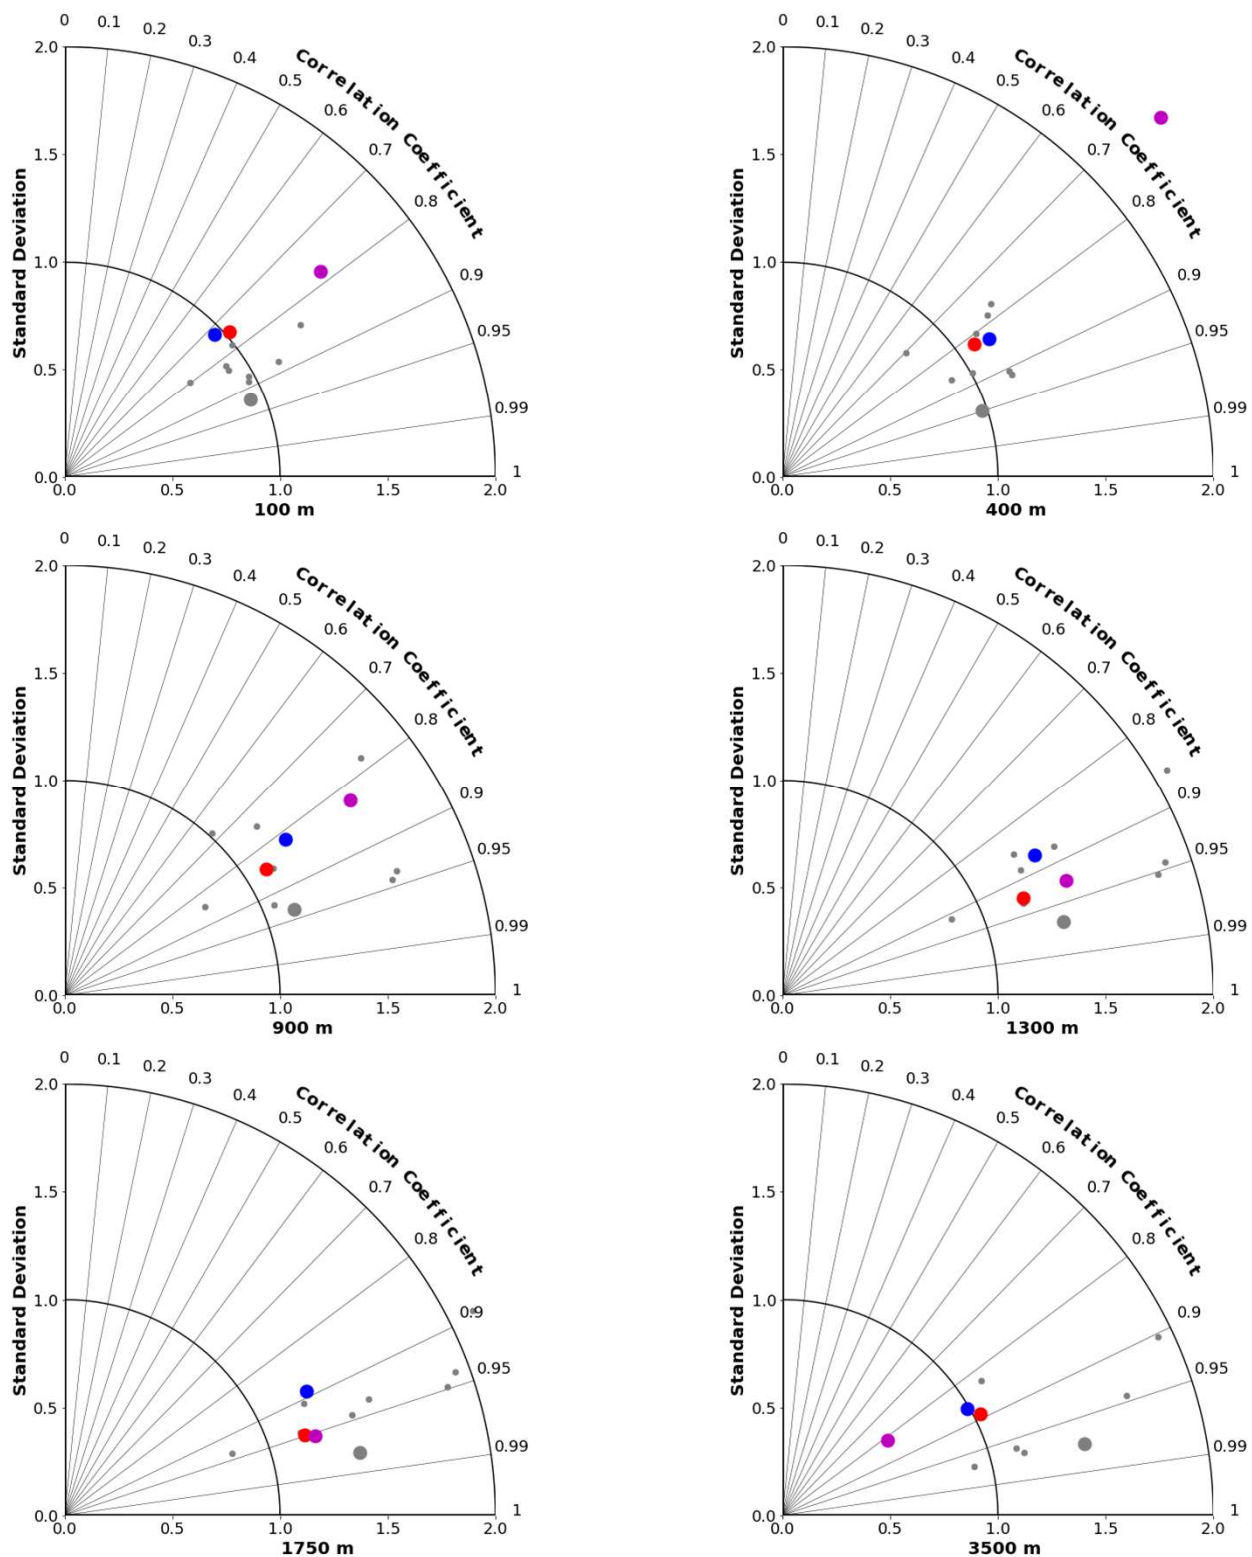

Figure 8 - Taylor diagrams comparing modelled and observed distributions of DIC at specific depths from 100 to 3500 m. Observations are from GLODAPv2 (Key et al., 2015; Lauvset et al., 2016). Red dots represent CanESM5-CanOE, blue dots CanESM5, magenta dots CanESM2, small grey dots other CMIP6 models, and large grey dots the model ensemble mean for all CMIP6 models except CanESM5 and CanESM5-CanOE.

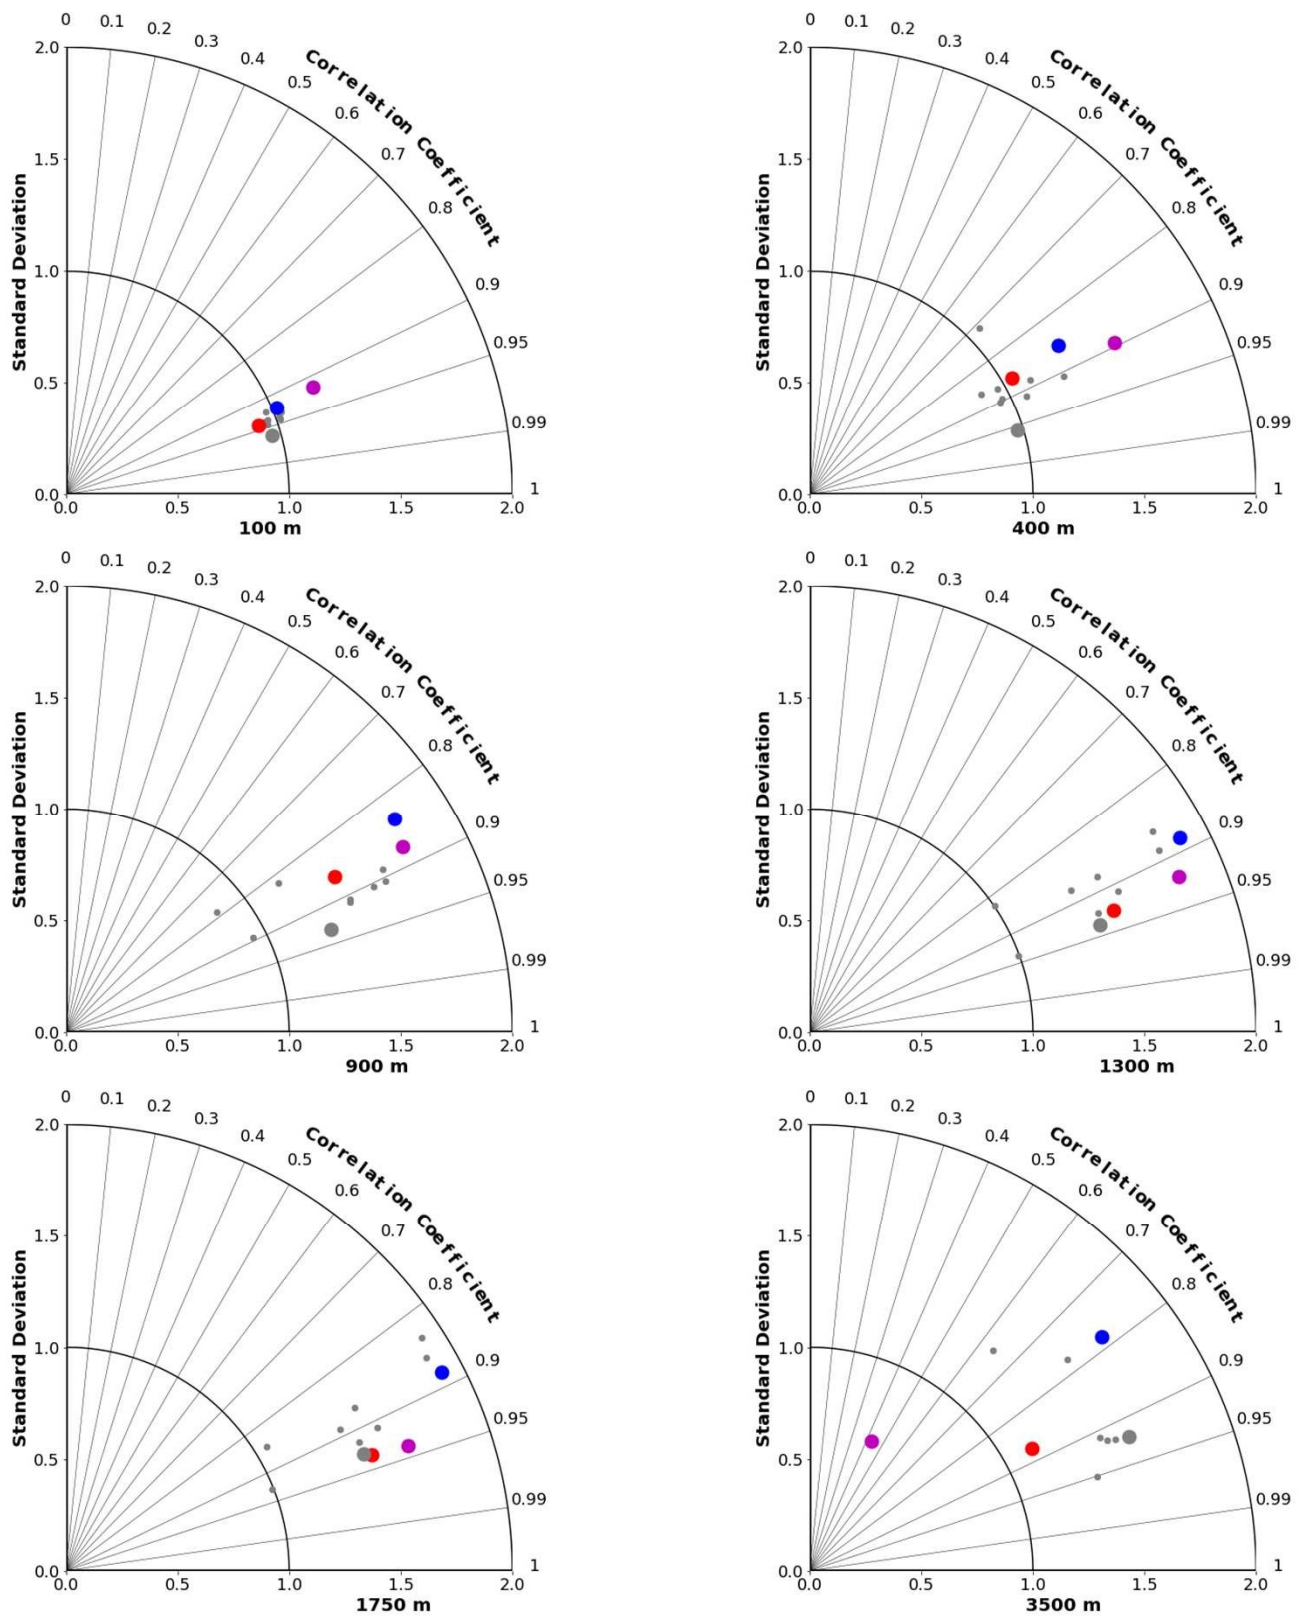

Figure 9 - Taylor diagrams comparing modelled and observed (GLODAPv2 + WOA2018) distributions of Ω_A at specific depths from 100 to 3500 m. Symbol colours as in Figure 8.

561 Taylor diagrams for a range of depths are shown for DIC in Figure 8 and for Ω_A in Figure 9 (for
562 alkalinity, see Supplementary Figure S4). As expected, the MEM generally compares favourably
563 with the individual models (e.g., Lambert and Boer, 2001). CanESM5 and CanESM5-CanOE
564 compare favourably with the full suite of CMIP6 models. CanESM5-CanOE shows a gain in
565 skill relative to CanESM5, and both show improvement relative to CanESM2. At 400 m,
566 CanESM2 stands out as having extremely high variance, which is mostly due to extremely high
567 DIC concentrations occurring over a limited area in the eastern equatorial Pacific (not shown).
568 This bias is present in CanESM5 and in CMIP6 models generally (Figure 6) but involves much
569 lower concentrations spread over a larger area.

570

571 **3.3 N and Fe cycles**

572

573 An important difference between CanESM5 and CanESM5-CanOE is the inclusion of a
574 prognostic Fe cycle. The CMOC iron mask (Zahariev et al., 2008) was a pragmatic solution in
575 the face of resource limitations but is inherently compromised as it can not evolve with a
576 changing climate. The first order test of a model with prognostic, interacting Fe and N cycles is
577 whether it can reproduce the distribution of HNLC regions and the approximate surface
578 macronutrient concentrations within these. CanESM5-CanOE succeeded by this standard,
579 although the surface nitrate concentrations are biased low in the subarctic Pacific and equatorial
580 Pacific and high in the Southern Ocean and in the global mean (Figure 10).

581

582 The seasonal cycle of the zonal mean surface nitrate concentration for a selection of CMIP6
583 models is shown in Figure 11. CanESM5, CanESM5-CanOE, and CNRM-ESM2-1 reproduce the

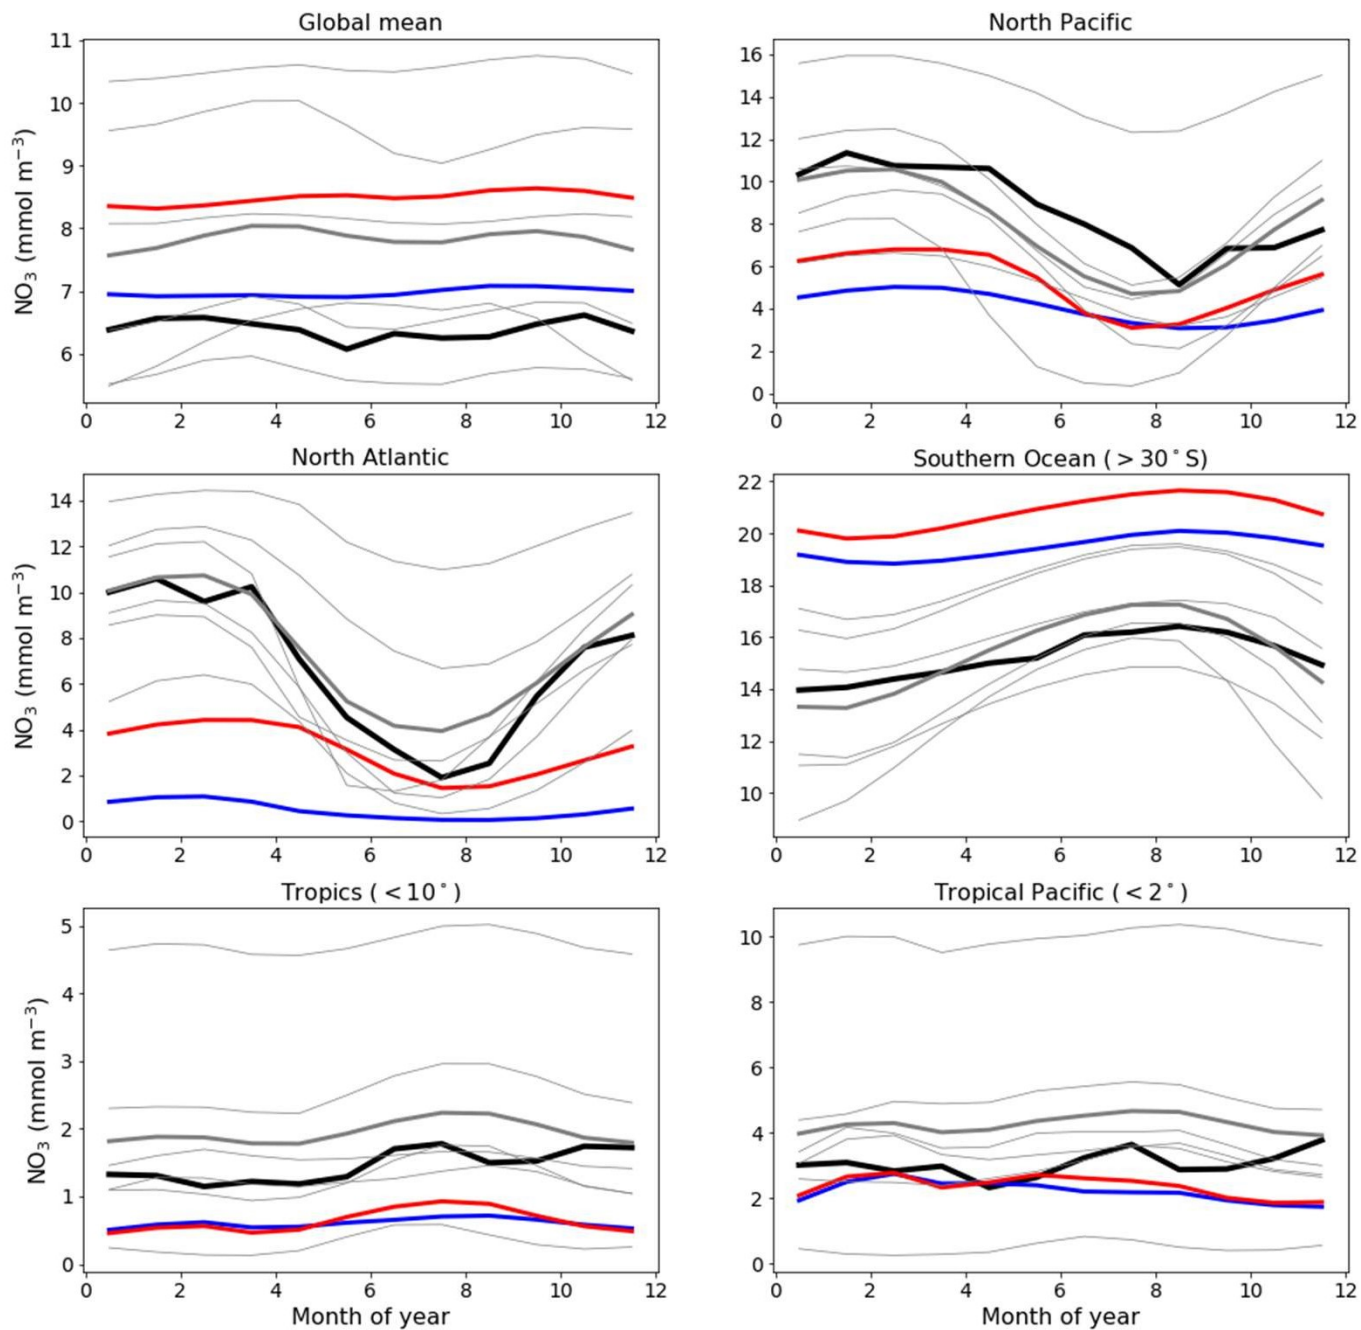

Figure 10 - Climatological seasonal cycle of surface nitrate concentration averaged for selected ocean regions. Thick red line represents CanESM5-CanOE, thick blue line CanESM5, thick black line observations (WOA2018), thin grey lines individual CMIP6 models, and thick grey line the model ensemble mean (excluding CanESM5 and CanESM5-CanOE). Regional boundaries are given in Supplementary Table S5 and Supplementary Figure S5.

Figure 11 - Climatological seasonal cycle of zonal mean surface nitrate concentration for a selection of CMIP6 models, a model ensemble mean (MEM) excluding CanESM5 and CanESM5-CanOE, and an observation-based data product (WOA2018). An alternate version showing only latitudes $<20^{\circ}$ is given in Supplementary Figure S6.

586 equatorial enrichment and the low concentrations in the tropical-subtropical latitudes fairly well.
587 Some models either have very weak equatorial enrichment (MPI-ESM1-2-LR) or too high a
588 concentration in the off-equatorial regions (UKESM1-0-LL, NorESM2-LM). UKESM1-0-LL
589 has very high concentrations throughout the low-latitude Pacific, which biases the ensemble
590 mean (Figure 11). Supplementary Figure S6 shows the same data as Figure 11 but for a more
591 limited latitude range to better illustrate model behaviour in the tropics. CanESM5, CanESM5-
592 CanOE, and CNRM-ESM2-1 reproduce the seasonal cycle of tropical upwelling (e.g., Philander
593 and Chao, 1991), with highest concentrations in summer.

594

595 The surface distribution of dissolved iron (dFe) in various CMIP6 models is shown in Figure 12.
596 For Fe there is no observation-based global climatology with which to compare the model
597 solutions (some comparisons to available profile data are shown in Supplementary Figures S10b-
598 h). CanESM5-CanOE shows a similar overall spatial pattern to other models, and generally falls
599 in the middle of the spread, particularly regarding concentrations in the Southern Ocean. Several
600 models show extremely high concentrations in the tropical-subtropical North Atlantic (Sahara
601 outflow region). CanESM5-CanOE, along with CNRM-ESM2-1 and CESM2, has much less
602 elevated concentrations in this region, due to lower deposition or greater scavenging or both.
603 CanESM5-CanOE has its lowest concentration in the eastern subtropical South Pacific, which is
604 common to many models (Figure 12). The area of strong surface depletion is generally more
605 spatially restricted in CanESM5-CanOE than in other models, and surface dFe concentrations are
606 greater over large areas of the Pacific. Both the north-south and east-west asymmetry of
607 distribution in the Pacific is greater in CanESM5-CanOE than in most other models, some of
608 which show the South Pacific minimum extending westward across the entire basin, and others

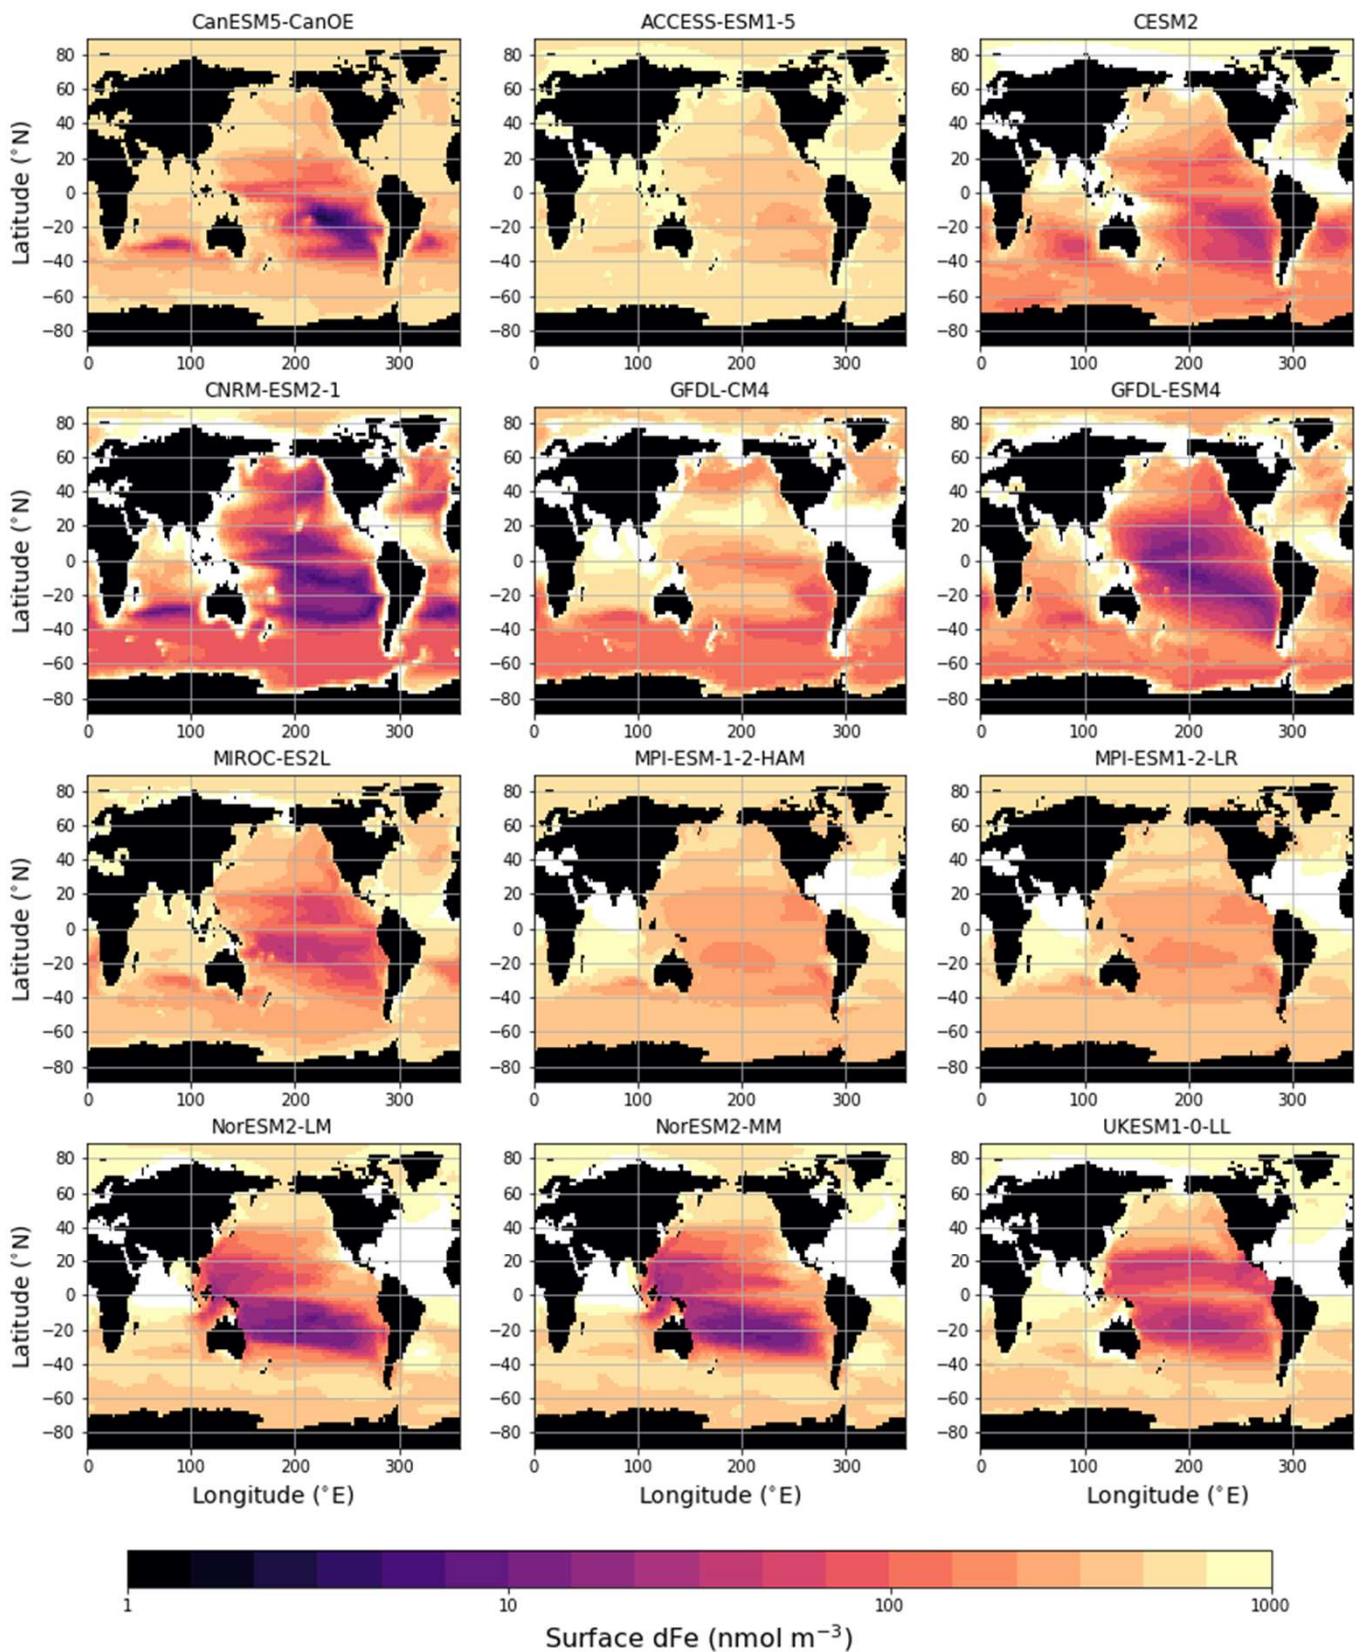

Figure 12 - Global distribution of dissolved iron (dFe) concentration (\log_{10} of concentration in nmol m^{-3}) at the ocean surface for CanESM5-CanOE and other CMIP6 models that published this field. Concentrations exceeding 1000 nmol m^{-3} are masked white. CanESM5 is not included because it does not have prognostic iron.

Figure 13 - Global mean depth profiles of dissolved iron concentration for CanESM5-CanOE and other CMIP6 models that published this field. GFDL-CM4 is excluded because it has very high concentrations ($>2000 \text{ nmol m}^{-3}$) near the surface. Thick red line represents CanESM5-CanOE, thin grey lines individual CMIP6 models, and the thick grey line the model ensemble mean (excluding CanESM5-CanOE and GFDL-CM4).

611 into the Northern Hemisphere. Only in CESM2 is this minimum similarly limited to the
612 southeast Pacific.

613
614 The mean depth profiles of dFe are shown in Figure 13. Some models show more of a “nutrient-
615 type” (increasing with depth due to strong near-surface biological uptake and subsequent
616 remineralization) profile, some a more “scavenged-type” (maximal at the surface, declining with
617 depth) profile (cf. Li, 1991; Nozaki, 2001), and others a hybrid profile (increasing downward but
618 with a surface enrichment). CanESM5-CanOE is at the “nutrient-type” end of spectrum with a
619 generally monotonic increase with depth to a near-constant deep-water concentration of 0.6 nM
620 and a very slight near-surface enrichment (see also Supplementary Figures S10b,c).

621
622 Mean surface nitrate and dFe concentrations for selected ocean regions are shown in Figure 14.
623 CanESM5-CanOE shows concentrations that are within the range of CMIP6 models, although in
624 some cases at the higher or lower end. Surface nitrate concentrations generally compare
625 favourably with the observation-based climatology, but are biased low in HNLC regions other
626 than the Southern Ocean. These biases are not necessarily a consequence of having too much or
627 too little iron. For example, in the Southern Ocean CanESM5-CanOE has among the highest
628 surface nitrate concentrations, but it also has some of the highest dFe concentrations, and the
629 high nitrate bias is present in CanESM5 as well. Comparisons with the limited GEOTRACES
630 data available suggest that near surface dFe concentrations in the Southern Ocean are biased high
631 rather than low in CanESM5-CanOE (not shown). One region where there does seem to be a
632 strong correlation between surface nitrate and dFe concentrations is the western subarctic
633 Pacific. All but two models (CNRM-ESM2-1, NorESM2-LM) fall along a spectrum from high

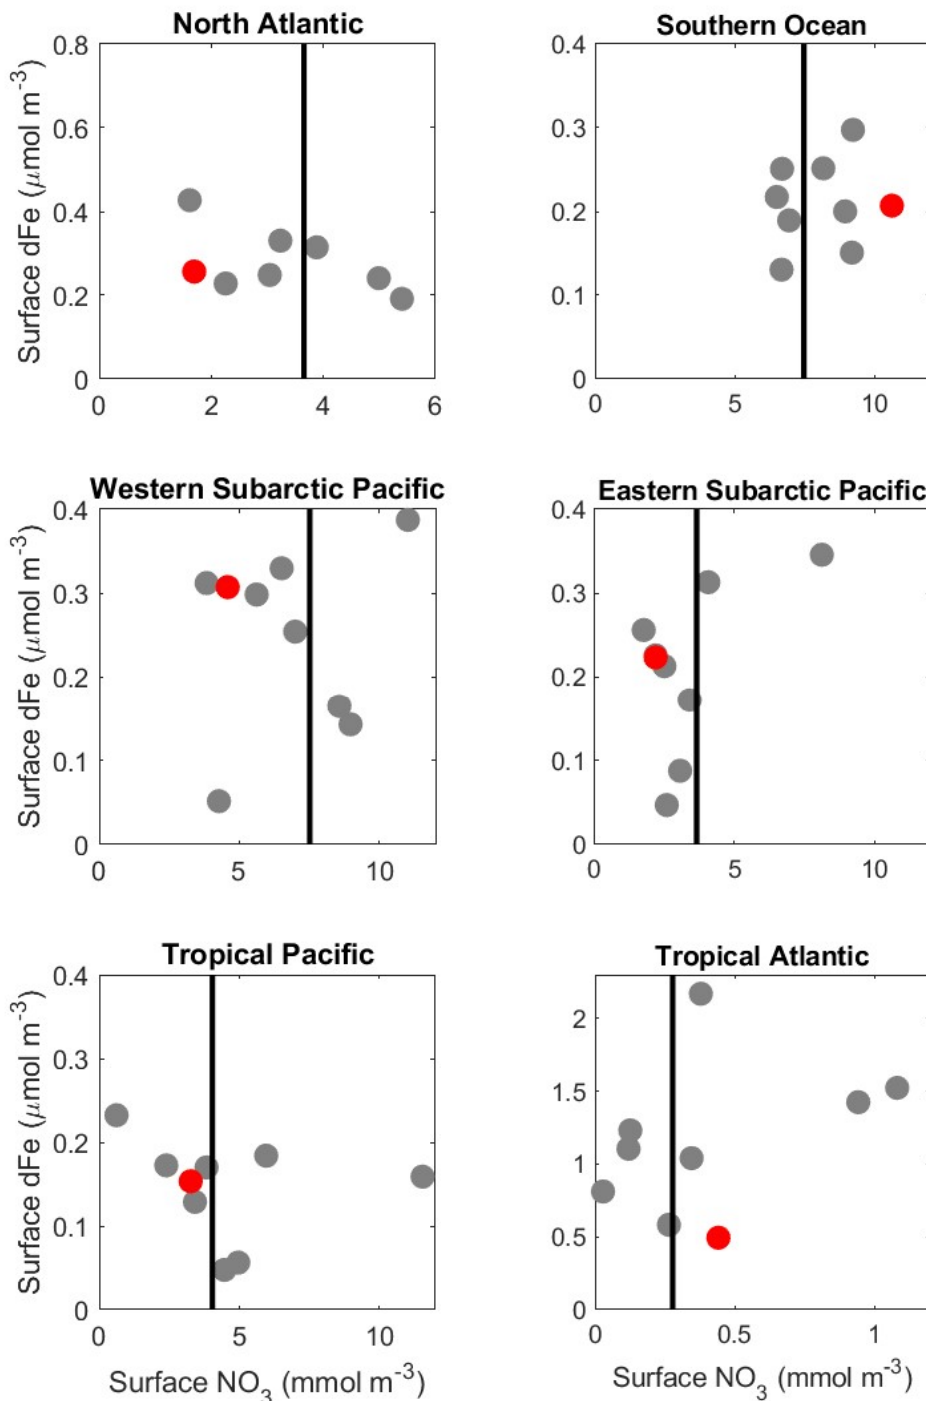

Figure 14 - Mean surface nitrate (NO_3) vs. dissolved iron (dFe) concentrations in different oceans, including the major high nutrient / low chlorophyll (HNLC) regions. CanESM5-CanOE is shown as a red dot and other CMIP5 models as grey dots (CanESM5 is not included because it does not have iron). Observed NO_3 is shown as a vertical black line as there are no observational estimates of dFe concentration. For GFDL-CM4, nitrate is estimated as phosphate x 16. Region definitions are given in Supplementary Table S5 and Supplementary Figure S5.

Figure 15 - Surface nitrate (NO₃) concentrations along the Pacific equator (mean from 2°S-2°N) during the upwelling season (June-October) for CanESM5-CanOE (red), CanESM5 (blue), and WOA2018 observations (black).

636 Fe / low nitrate to low Fe / high nitrate. CanESM5-CanOE falls near the high Fe / low nitrate end
637 of the range.

638
639 Surface nitrate concentrations along the Pacific equator during the upwelling season (June-
640 October) for CanESM5 and CanESM5-CanOE are shown in Figure 15. The range of other
641 CMIP6 models is not shown here because it is large and therefore adds little information (see
642 Figure 11 and Supplementary Figure S6). CanESM5-CanOE better represents the east-west
643 gradient, while CanESM5 has slightly higher concentrations in the core upwelling region. Both
644 models underestimate the highest concentrations around 100°W. Although some localized
645 maxima in this data product are due to undersampling, equatorial upwelling is strong at this
646 location (e.g., Lukas, 2001) and the spatial coherence of the data strongly suggests that this
647 maximum accurately reflects reality. It should be noted that CanESM5 iron limitation is
648 calculated from a version of the same data product; however, the Fe mask is based on the
649 minimum nitrate concentration over the annual cycle, whereas the data shown here are for the
650 upwelling season.

651

652 **3.4 Plankton biomass, detritus, and particle flux**

653

654 The relative abundance of the four plankton groups are shown in Figure 16 for a range of ocean
655 regions. Both CanESM models mostly compare favourably with observation-based estimates of
656 phytoplankton biomass, except in the tropics where CanESM5-CanOE has very high biomass.
657 Both CanESM models have low phytoplankton biomass in the North Atlantic. In the North
658 Pacific and the Southern Ocean, CanESM5-CanOE reproduces the observation-based estimates

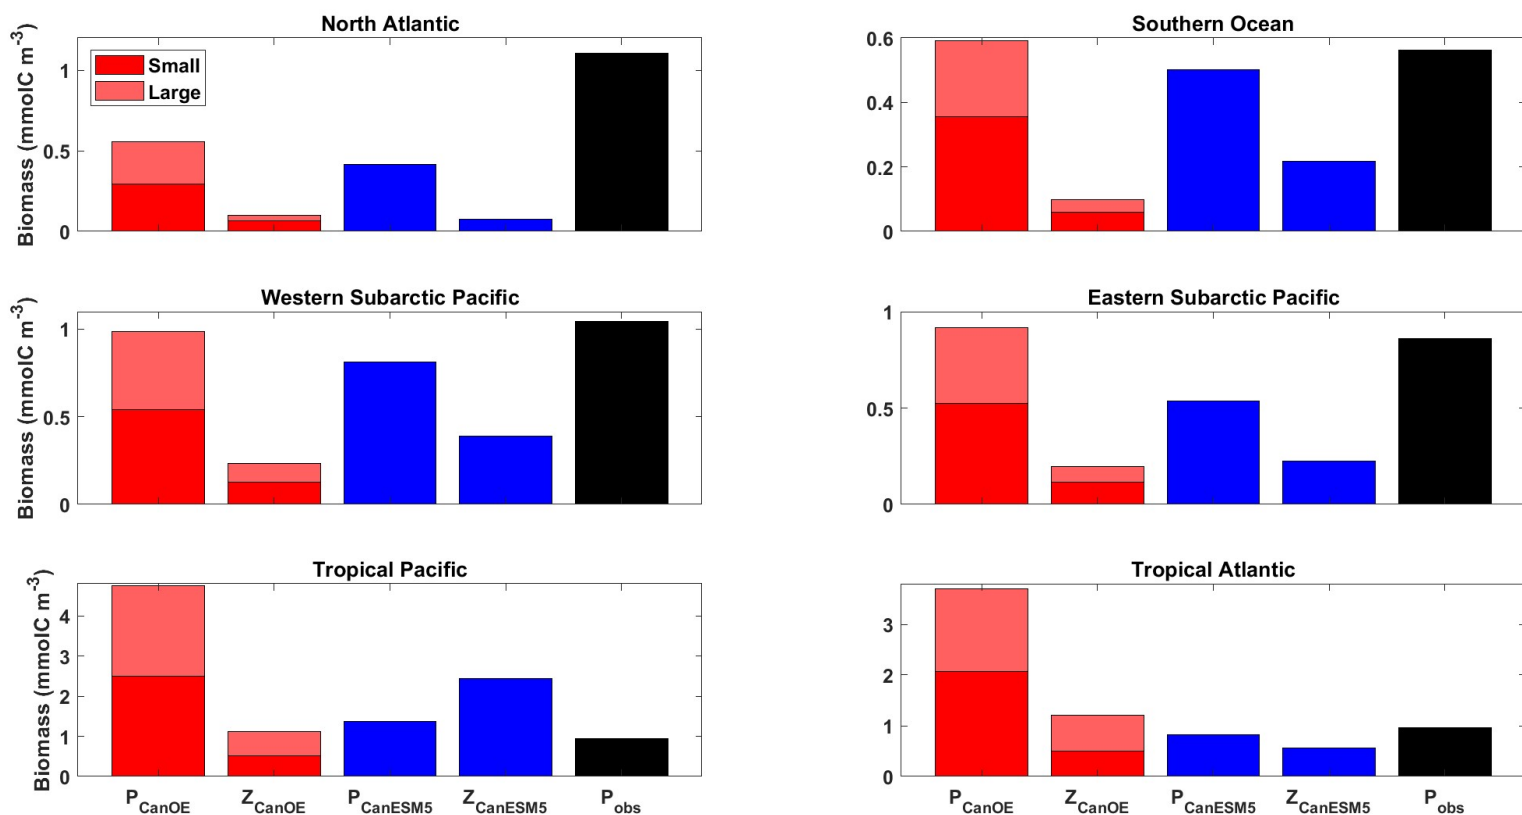

Figure 16 - Annual mean surface ocean concentration of large and small phytoplankton and zooplankton in CanESM5-CanOE (red) and of phytoplankton and zooplankton in CanESM5 (blue) for the representative ocean regions shown in Figure 14. Observational estimates (black) are for phytoplankton biomass calculated from satellite ocean colour estimates of surface chlorophyll (SeaWiFS/MODIS; Tesdal et al. 2016), assuming a carbon-to-chlorophyll ratio of 50 g/g. Region definitions are given in Supplementary Table S5 and Supplementary Figure S5.

660 well, and CanESM5 slightly less well. The general pattern is that large and small phytoplankton
661 have similar abundance, and are substantially more abundant than zooplankton.

662

663 Part of the rationale for multiple food chains is that they better represent the way that actual
664 plankton communities adapt to different physical ocean regimes and therefore are better able to
665 simulate distinct ocean regions with a single parameter set (e.g., Chisholm, 1992; Armstrong,
666 1994; Landry et al., 1997; Friedrichs et al., 2007). The expectation is that small phytoplankton
667 will be more temporally stable and large phytoplankton will fluctuate more strongly between
668 high and low abundances. The mean annual cycles of surface chlorophyll largely conform to this
669 pattern, e.g., in the North Atlantic and the western subarctic Pacific large phytoplankton are
670 dominant in summer and much more variable over the seasons (Figure 17). Compared to
671 observations, CanESM5 models underestimate the amplitude of the seasonal cycle in the North
672 Atlantic and overestimate it in the North Pacific. CanESM5 shows a stronger and earlier North
673 Atlantic spring bloom compared to CanESM5-CanOE; the observations are in between the two
674 in terms of timing, and both models underestimate the amplitude (Figure 17). In the tropics, the
675 seasonal cycle is weak. CanESM5-CanOE in the tropical Atlantic shows the expected seasonal
676 cycle but not the expected dominance of large phytoplankton in summer. CanESM5-CanOE
677 generally overestimates the total near surface chlorophyll in both the tropical Pacific and the
678 tropical Atlantic.

679

680 Zooplankton biomass (especially microzooplankton) is also somewhat difficult to test against
681 observations, but our model concentrations appear to be biased low. Stock et al. (2014) estimated
682 depth-integrated biomass of phytoplankton, mesozooplankton, and microzooplankton for a range

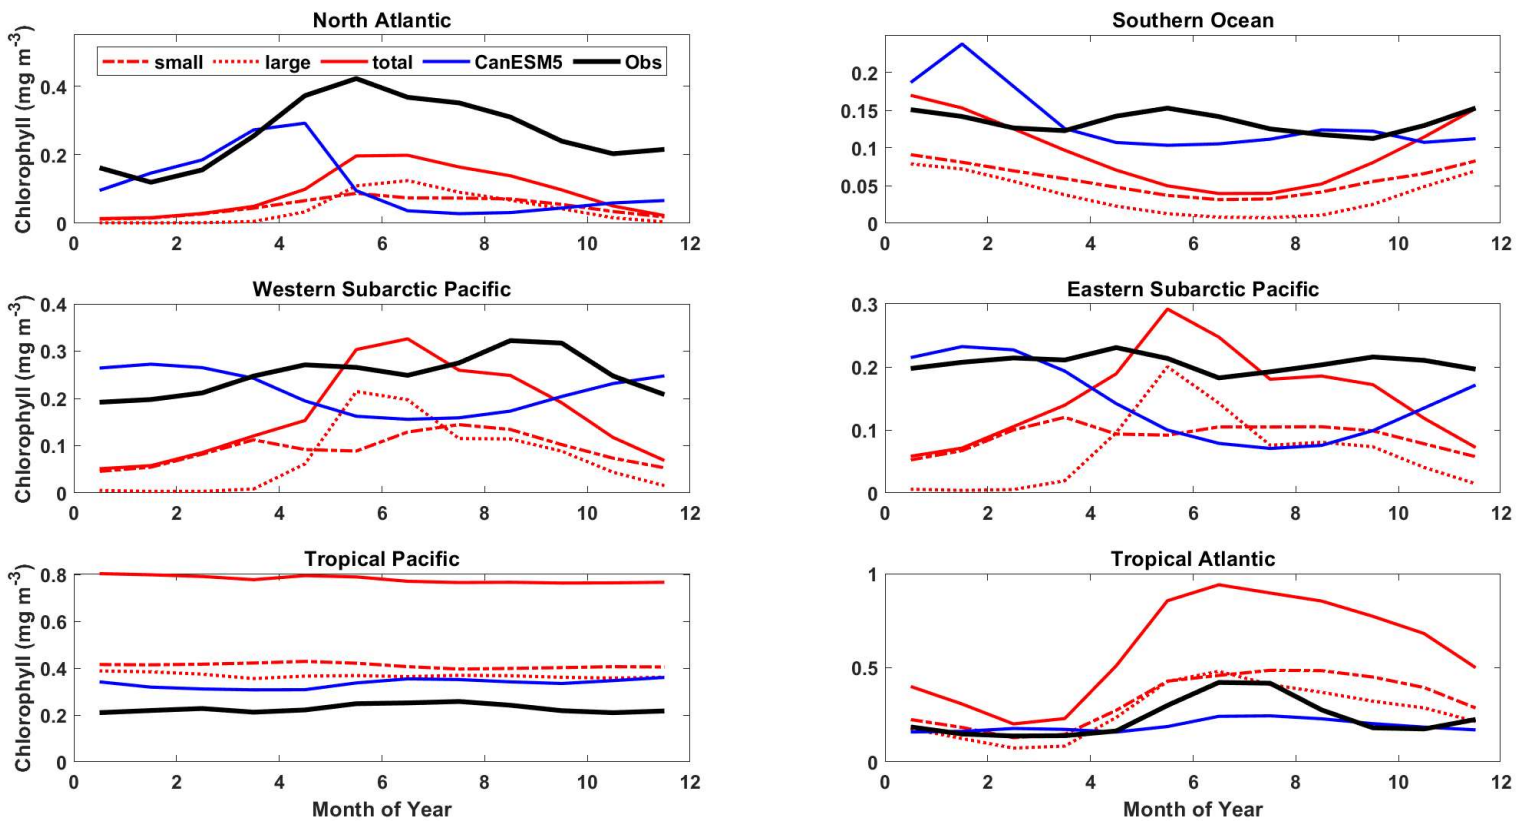

Figure 17 - Mean annual cycle of surface chlorophyll for the representative ocean regions shown in Figures 14 and 16. CanESM5-CanOE large and small phytoplankton concentrations are shown separately and combined (red) along with CanESM5 (blue) and observational estimates (black). Region definitions are shown in Supplementary Table S5 and Supplementary Figure S5.

684 of oceanic locations in which intensive field campaigns have occurred (estimates of
685 microzooplankton biomass are relatively sparse). They found that in most locations
686 phytoplankton and (combined) zooplankton biomass are of comparable magnitude, whereas in
687 CanESM5-CanOE zooplankton biomass is consistently lower (Figure 16). The global integral
688 biomass of mesozooplankton is about an order of magnitude less than the 0.19 PgC estimated by
689 Moriarty and O'Brien (2013). The CanESM5 total of 0.14 Pg is relatively close to the Moriarty
690 estimate but implicitly includes microzooplankton.

691

692 Surface chlorophyll and POC for CanESM5-CanOE and for ocean colour observational data are
693 shown in Figure 18 (POC in the model is the sum of phytoplankton, microzooplankton, and
694 detrital carbon). The observations have a lower limit for POC that is not present in the model
695 ($\sim 17 \text{ mgC m}^{-3}$), which is unsurprising given the processes neglected in the model, i.e., in regions
696 of very low chlorophyll there is still substantial dissolved organic carbon, bacteria that consume
697 it, and microzooplankton that consume the bacteria and produce particulate detritus. The
698 observational data show a fairly linear relationship at low concentrations, but with a curvature
699 that implies a greater phytoplankton fraction in more eutrophic environments (cf. Chisholm,
700 1992). The model, by contrast, shows a fairly linear relationship over the whole range of
701 concentrations. In other words, the phytoplankton share of POC is higher and more constant in
702 the model than in the observations. The living biomass (phytoplankton + microzooplankton)
703 fraction of total POC in CanOE is generally in excess of 50% (not shown), which is implausible
704 for a real-world oceanic microbial community (e.g., Christian and Karl, 1994) but consistent
705 with the relatively low rates of export from the euphotic zone.

706

Figure 18 - Climatological surface particulate organic carbon (POC) vs. chlorophyll for CanESM5-CanOE (red) and observations (black). Data are for all ocean grid points ($2 \times 2^\circ$ uniform global grid) for all months of the year where observational data are available. Model POC is offset 17 mg m^{-3} for illustrative purposes. Chlorophyll concentrations $>1 \text{ mg m}^{-3}$ are excluded as they largely represent coastal areas poorly resolved by coarse resolution global ocean models.

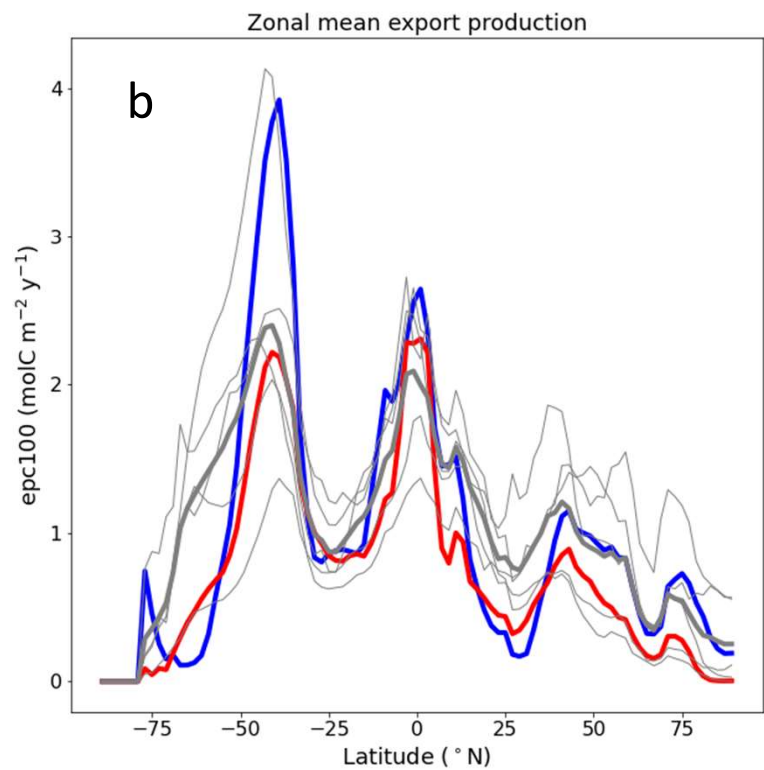

Figure 19 - (a) Global total export production (epc100) in PgC y⁻¹ (b) and zonal mean export production in molC m⁻² y⁻¹ according to selected CMIP6 models (mean for 1985-2014 of historical experiment). Thick red line represents CanESM5-CanOE, thick blue line CanESM5, thin grey lines individual CMIP6 models, and thick grey line the model ensemble mean (excluding CanESM5 and CanESM5-CanOE).

710 Export production for a range of CMIP6 models is shown in Figure 19a. CanESM5-CanOE is at
711 the low end of the range. Observations are not shown because the range of observational
712 estimates covers the entire range of model estimates (e.g., Siegel et al., 2016). Note also that
713 CanESM5 export is quite a bit lower than in CanESM2, which is relatively high for CMIP5
714 models (not shown). The difference between CanESM2 and CanESM5 is attributable primarily
715 to different circulation, although the different initialization fields for nitrate might also play a
716 small role. The lower rate in CanESM5-CanOE is consistent with the above results regarding
717 plankton community structure (e.g., the concentration of detritus is generally low compared to
718 living biomass), as well as the lower sinking rate for small detritus. The latitudinal distribution of
719 export is shown in Figure 19b. CanESM5 shows very high export in the mid-latitudes of the
720 Southern Ocean, similar to CanESM2 (not shown). Both CanESM5 and CanESM5-CanOE show
721 latitudinal patterns consistent with the range of other CMIP6 models. CanESM5 has slightly
722 greater export in the equatorial zone; in both CanESM5 and CanESM5-CanOE the equatorial
723 enrichment attenuates very rapidly with latitude and the rates are low in the subtropics.

724

725 **3.5 Historical trends**

726

727 Cumulative ocean uptake of CO₂ is shown in Figure 20 for the historical experiment (1850-
728 2014). CanESM models are biased low relative to observation based estimates (~145 PgC, see
729 Friedlingstein et al., 2020) and the MEM (144 PgC, Figure 20), but fall well within the spread of
730 CMIP6 models. Some of the difference may be attributable to differences in the way cumulative
731 uptake is calculated in models vs observations (Bronse laer et al., 2017), although this should
732 apply to other CMIP6 models as well. CanESM5-CanOE has lower cumulative uptake than

Figure 20 - Cumulative ocean uptake of carbon dioxide (CO₂) as anthropogenic dissolved inorganic carbon (AnthDIC) in PgC over the course of the historical experiment (1850-2014). Data are shown as successive five-year means. CMIP6 mean (thick grey line) indicates ensemble mean for CMIP6 models (thin grey lines) excluding CanESM5 (blue) and CanESM5-CanOE (red). An observation-based estimate of 145 ± 20 PgC (Friedlingstein et al., 2020) is shown for nominal year 2014 (black).

Figure 21 - Change in export production (epc100) over the course of the historical experiment (1850-2014), normalized to the 1850-1900 mean. Data are shown as successive five-year means. Thick red line represents CanESM5-CanOE, thick blue line CanESM5, thin grey lines other CMIP6 models, and thick grey line the ensemble mean of non-CanESM models.

735 CanESM5 by ~10 PgC. As the models were not fully equilibrated when the historical run was
736 launched, this difference does not necessarily arise from the biogeochemical model structure;
737 part of the difference can be attributed to differences in the spinup (cf. Séférian et al., 2016). The
738 drift in the piControl experiment over the 165 years from the branching off of the historical
739 experiment is -10.0 PgC in CanESM5-CanOE and -5.1 PgC in CanESM5 (see Supplementary
740 Table S6), so drift accounts for about half (48%) of the difference in net ocean CO₂ uptake. The
741 spatial distribution of anthropogenic DIC is very similar between CanESM5 and CanESM5-
742 CanOE (Supplementary Figure S7). CanESM5 and CanESM5-CanOE show a high bias in near
743 surface DIC relative to alkalinity (a measure of the ocean's capacity to absorb CO₂) in the mid-
744 latitudes of both hemispheres (Supplementary Figure S8), which may in part explain the weak
745 uptake of CO₂.

746

747 The long-term trend in global total export production is shown in Figure 21. The model values
748 must be normalized in order to compare trends, since the differences among means are large
749 compared to the changes over the historical period (Figure 19). Such trends are difficult or
750 impossible to meaningfully constrain with observations, but the general expectation has been that
751 export will decline somewhat due to increasing stratification (e.g., Steinacher et al., 2010).
752 CanESM5 shows a greater decline than most other CMIP6 models, while CanESM5-CanOE is
753 more similar to non-CanESM models. The change in CanESM5 is geographically widespread
754 and not concentrated in a specific region or regions: export is maximal in the tropics and the
755 northern and southern mid-latitudes (Figure 19b) and declines over the historical period in all of
756 these regions (Supplementary Figure S9). In CanESM5-CanOE, export declines in the same
757 regions, but the magnitude of the change is smaller, and in the Southern Ocean increases and

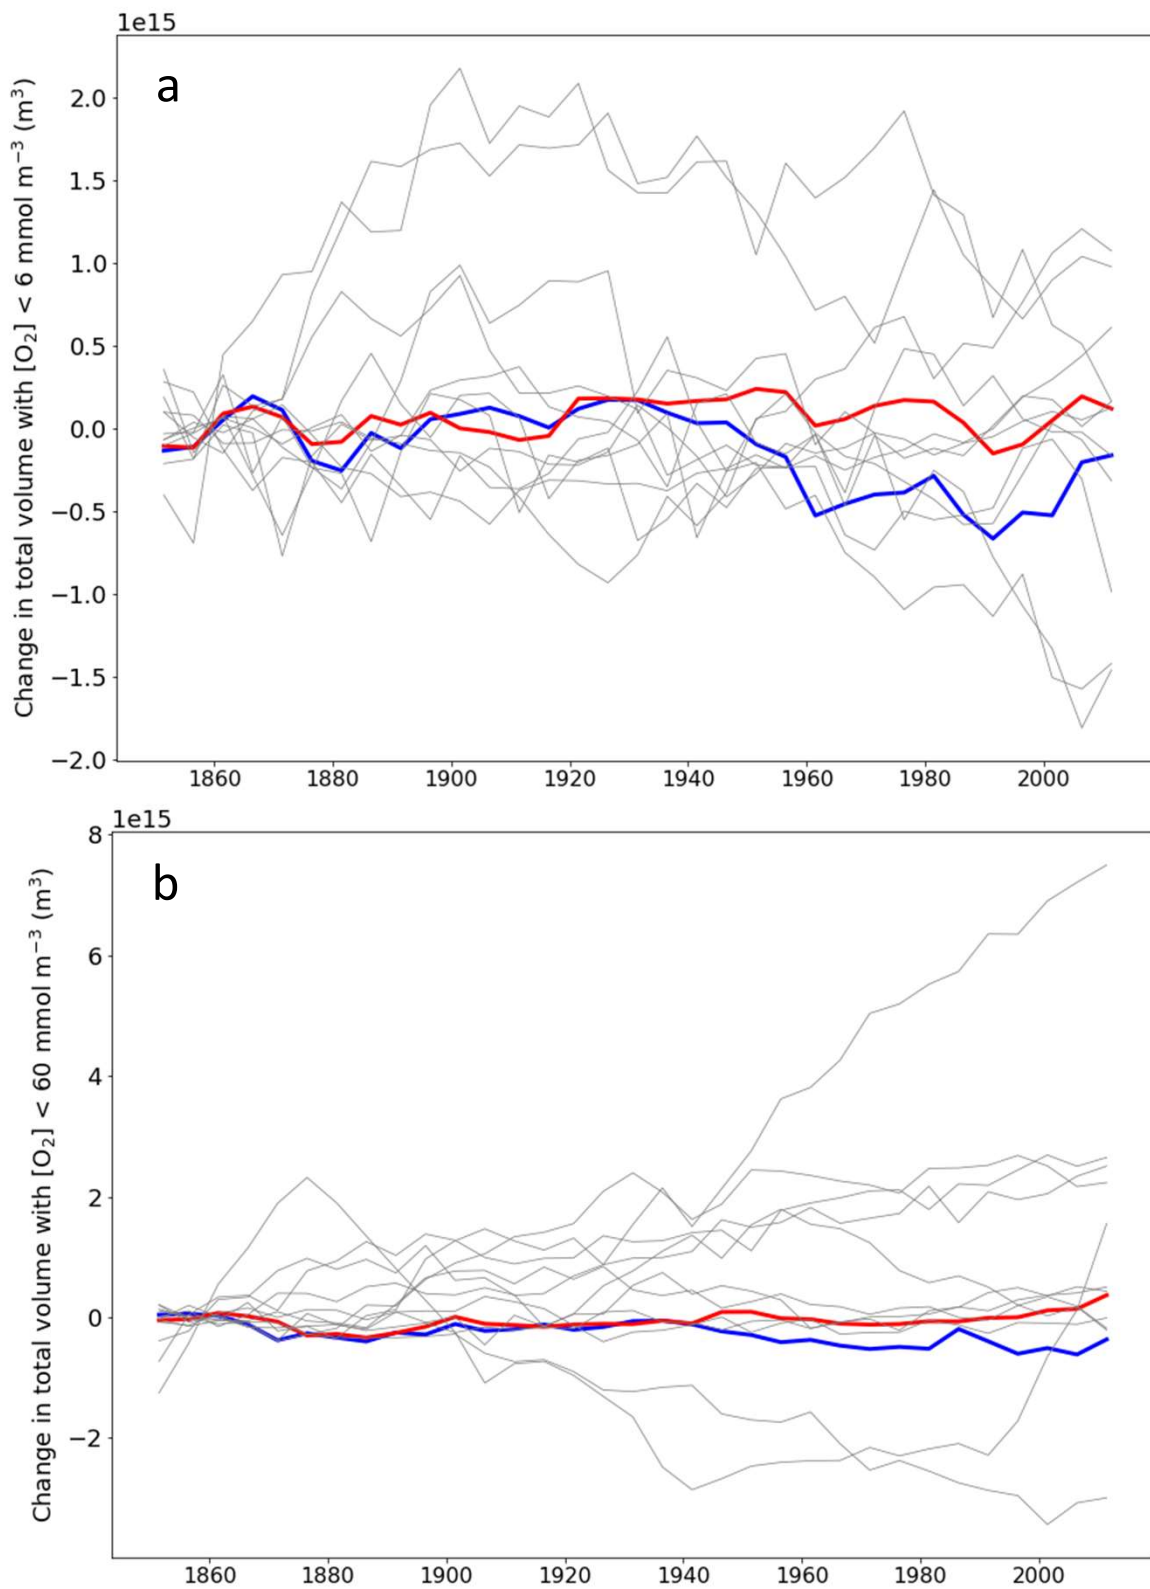

Figure 22 - (a) Change in total ocean volume with oxygen (O_2) concentration less than (a) 6 mmol m^{-3} and (b) 60 mmol m^{-3} over the course of the historical experiment (1850-2014), normalized to the 1850-1870 mean. Data are shown as successive five-year means. Thick red line represents CanESM5-CanOE, thick blue line CanESM5, and thin grey lines other CMIP6 models.

759 decreases in different latitude bands largely offset each other.

760

761 The trend in the volume of ocean water with O₂ concentration less than 6 or 60 mmol m⁻³ is
762 shown in Figure 22. Again, the totals are normalized to a value close to the preindustrial, as the
763 differences among models are large (Figure 5). For the volume with <60 mmol m⁻³, CanESM
764 models show relatively little change; in CanESM5 the volume actually declines slightly, while in
765 CanESM5-CanOE it increases, but the total change is <1% in each case. As with the baseline
766 volumes, the range among models is large, with one model showing an increase approaching
767 10% of the total volume estimated for WOA2018 (Figures 5b and 22b). For the volume with <6
768 mmol m⁻³ (Figure 22a), CanESM models are among the most stable over time. In CanESM5, the
769 volume again declines, although this is within the range of internal variability. Again some
770 models show fairly large excursions, but in this case none shows a strong secular trend over the
771 last half-century.

772

773 **4. Discussion**

774

775 CanESM5 and CanESM5-CanOE are new coupled ocean-atmosphere climate models with
776 prognostic ocean biogeochemistry. The two have the same physical climate (in experiments with
777 specified atmospheric CO₂) and differ only in their ocean biogeochemistry components.

778 CanESM5-CanOE has a much more complex biogeochemistry model including a prognostic iron
779 cycle. We have presented results that assess how these two models simulate the overall
780 distribution of major tracers like DIC, alkalinity, nitrate and oxygen, as well as analyses of the

781 interaction of the iron and nitrogen cycles, plankton community structure, export of organic
782 matter from the euphotic zone, and historical trends over 1850-2014.

783

784 The overall distribution of major tracers indicates that both models do a reasonable job of
785 simulating both biogeochemical (e.g., export and remineralization of organic matter) and
786 physical (e.g., deep and intermediate ocean ventilation) processes. The volume of ocean with
787 oxygen concentration below 6 or 60 μM compares favourably with other CMIP6 models (Figure
788 5), and is among the most stable over historical time (Figure 22). CanESM5-CanOE has a
789 substantially lower volume of water with $[\text{O}_2] < 6 \mu\text{M}$ than CanESM5 and much closer to
790 observation-based estimates (Figure 22a). Both models are biased slightly low in terms of
791 historical uptake of anthropogenic CO_2 , which may indicate weak Southern Ocean upwelling or
792 too shallow remineralization of DIC or both (Figure 20). The spatial distribution of
793 anthropogenic DIC is very similar between the two models (Supplementary Figure S7), which is
794 expected as it is mainly a function of the physical ocean model circulation. However, CanESM5
795 has higher concentrations in the main areas of accumulation, particularly the North Atlantic and
796 the Southern Ocean. This probably indicates more efficient removal and export of 'natural' DIC
797 by the plankton, particularly in the Southern Ocean upwelling zone (Figure 19), and deeper
798 average remineralization, with the caveat that the preindustrial control simulations had different
799 degrees of equilibration when the historical experiment was launched (cf. Séférian et al., 2016,
800 Supplementary Table S6).

801

802 Analysis of phytoplankton and zooplankton biomass concentrations show that CanESM5 and
803 CanESM5-CanOE compare somewhat favourably with available observational data but do have

804 distinct biases. In particular, both zooplankton biomass and detrital organic matter concentration
805 tend to be very low in CanESM5-CanOE; the total biomass of the plankton community and the
806 standing crop of particulate organic matter are dominated by phytoplankton (e.g., Figure 17).
807 Regional biases differ between the two models, with CanESM5-CanOE showing excessively
808 large phytoplankton biomass in the tropics. We note, however, that the seasonal cycle of
809 equatorial upwelling and the formation of the equatorial Pacific HNLC are reproduced rather
810 well by our models (e.g., Figures 11, 15 and S6), and that CanESM5-CanOE is the first CanESM
811 model to have genuinely simulated this as an emergent property (see section 3.3). In CanESM5-
812 CanOE, decoupling of large and small phytoplankton populations associated with seasonal
813 upwelling or convection (see below) is observed in some regions but not others.

814

815 Global export production is biased low, particularly in CanESM5-CanOE. This is due in part to
816 the biogeochemical model and in part to ocean circulation. CanESM5 has the same ocean
817 biology as CanESM2 but a different physical ocean model, and global ocean export production is
818 substantially lower in CanESM5. It is lower still in CanESM5-CanOE (Figure 19). We note that
819 CanESM5 performs better than CanESM2 on most metrics of physical ocean model evaluation
820 (Swart et al., 2019a), and shows a more realistic distribution of major tracers like DIC (Figure 8).
821 While the range of observation-based estimates of global ocean export production is large, and
822 encompasses the full range of CMIP5 and CMIP6 models, the change between CanESM2 and
823 CanESM5 is large. Changes in the physical ocean are not entirely independent of the
824 biogeochemistry model even when the latter is ostensibly identical. In CanESM2 and CanESM5,
825 iron limitation is specified as a spatially static 'mask' based on the observed distribution of
826 surface nitrate, and it is possible that in these two models ocean upwelling occurs in different

827 places relative to the specified boundary of the region of Southern Ocean iron limitation (Figure 3
828 of Zahariev et al., 2008). It is also possible that the lower export production in CanESM5-CanOE
829 is due to low iron supply to the surface waters of the Southern Ocean, but comparison with
830 available observations do not suggest that this is the case. Several biases are common to
831 CanESM5 and CanESM5-CanOE that relate to Southern Ocean upwelling (high Southern Ocean
832 surface nitrate concentration, low export production, weak anthropogenic CO₂ uptake) and so are
833 probably more attributable to the physical ocean model than to the Fe submodel. The difference
834 between CanESM2 and CanESM5 bears this out.

835

836 The development of CanOE was undertaken in response to some of the most severe limitations
837 of CanESM2. Many of the additional features that CanOE introduces were already in the models
838 published by other centres even in CMIP5. In addition to CMOC (Zahariev et al., 2008),
839 previous models developed by members of our group include Denman and Peña (1999; 2002),
840 Christian et al. (2002a; 2002b), Christian (2005), and Denman et al. (2006). Christian et al.
841 (2002a) had a prognostic Fe cycle and multiple phytoplankton and zooplankton species, but had
842 fixed elemental ratios. Christian (2005) incorporated a cellular-regulation model, but only for a
843 single species and without Fe limitation. Christian (2005) had prognostic chlorophyll whereas
844 Denman and Peña (1999; 2002) and Christian et al. (2002a) used an irradiance-dependent
845 diagnostic formulation. Christian et al. (2002a) used multiplicative (Franks et al., 1986) grazing,
846 which creates stability in predator-prey interactions but severely limits phytoplankton biomass
847 accumulation under nutrient-replete conditions.

848

849 One of the most important lessons from Christian et al. (2002a; 2002b) was that when a fixed
850 Fe/N ratio is employed, sensitivity to this parameter is extreme. Because Fe cell quotas are far
851 more variable than N, P, or Si quotas, treating this parameter as constant results in the specified
852 value influencing the overall solution far more than any other parameter. CanESM5-CanOE
853 largely succeeded in creating a prognostic Fe-N limitation model that produces HNLC conditions
854 in the expected regions (Figures 10, 11, 14, 15, S6), although surface nitrate concentration is low
855 relative to observation-based estimates in some cases. External Fe sources and scavenging
856 parameterizations will be revisited and refined in future versions. In CanESM5-CanOE the
857 scavenging model is very simple, with distinct regimes for concentrations greater or less than 0.6
858 nM; scavenging rates are very high above this threshold which causes deep-water concentrations
859 to converge on this value. The generally nutrient-like profile suggest that in CanOE the
860 scavenging rate is quite low for concentrations below 0.6 nM (Figure 13; see also Supplementary
861 Figure S10h). We note that the aeolian mineral dust deposition field employed here is derived
862 from the CanESM atmosphere model; these processes are not presently interactive but could be
863 made so in the future.

864

865 A particular issue with CanESM2 was that extremely high concentrations of nitrate occurred
866 under the EBC upwelling regions. This error resulted from spreading denitrification out over the
867 ocean basin so that introduction of new fixed N from N₂ fixation would balance denitrification
868 losses within each vertical column, whereas in the real world denitrification is highly localized in
869 the low oxygen environments under the EBCs. CanESM2 did not include oxygen, but CanESM5
870 incorporates oxygen as a ‘downstream’ tracer that does not feed back on other biogeochemical
871 processes. The incorporation of a more process-based denitrification parameterization in

872 CanESM5-CanOE is independent of the many other processes that are present in CanESM5-
873 CanOE but not in CanESM5: a CMOC-like model with prognostic denitrification is clearly an
874 option. We chose not to include explicit, oxygen-dependent denitrification in CanESM5 because
875 we wanted to maintain a CMOC-based model as close to the CanESM2 version as possible, and
876 because oxygen would not then be a downstream tracer that does not affect other processes.

877

878 Plankton community structure in CanESM5-CanOE is somewhat biased toward high
879 concentrations of phytoplankton, low concentrations of zooplankton and detritus, and low export
880 (Sect. 3.4). In the development phase, a fair number of experiments were conducted with various
881 values of the grazing rates and detritus sinking speeds. A wide range of values of these
882 parameters was tested, with no resulting improvement in the overall results. Possibly the detrital
883 remineralization rates are too high, although primary production is also on the low end of the
884 CMIP6 range (not shown), and would probably decline further if these rates were decreased. The
885 model was designed around the Armstrong (1994) hypothesis of ‘supplementation’ vs
886 ‘replacement’, i.e., small phytoplankton and their grazers do not become much more abundant in
887 more nutrient-rich environments but rather stay at about the same level and are joined by larger
888 species that are absent in more oligotrophic conditions (see also Chisholm, 1992; Landry et al.,
889 1997; Friedrichs et al., 2007). The results presented here suggest that this was partially achieved,
890 but further improvement is possible (Figure 17).

891

892 As to whether the gains in skill with CanESM5-CanOE justify the extra computational cost,
893 Taylor diagrams (Figures 4, 8, 9, and Supplementary Figure S4) show a modest but consistent
894 gain in skill at simulating the major biogeochemical species (O₂, DIC, alkalinity) across

895 variables and depths, especially for alkalinity at mid-depths (Supplementary Figure S4), for
896 which CanESM5 displays the least skill relative to other fields or depths. Other processes that are
897 highly parameterized in CanESM5, such as calcification and CaCO_3 dissolution, were not
898 addressed in detail in this paper, but are an important factor in determining the subsurface
899 distribution of alkalinity. Again, we emphasize that we are simulating as an emergent property of
900 a process-based model something that is parameterized in CanESM5 (as previously noted for
901 surface nitrate concentration in HNLC regions), and doing at least as well in terms of model
902 skill. As a general rule, the potential for improving skill and achieving better results in novel
903 environments (e.g., topographically complex regional domains like the Arctic Ocean and the
904 boreal marginal seas), is expected to be greater in less parameterized, more mechanistic models
905 (e.g., Friedrichs et al., 2007; Tesdal et al., 2016). Inclusion of a prognostic iron cycle and C/N/Fe
906 stoichiometry also open up additional applications and scientific investigations that are not
907 possible with CMOC.

908

909 An updated version of CanESM5 with prognostic denitrification is clearly possible. However, for
910 the reasons discussed above, a prognostic Fe cycle with a fixed phytoplankton Fe/N remains
911 problematic, and the model would still have a single detritus sinking speed and remineralization
912 length scale. We are also developing CanOE for regional downscaling applications (Hayashida,
913 2018; Holdsworth et al., 2021). The regional domains have complex topography and prominent
914 continental shelf and slope, and the single remineralization length scale in CMOC may not be
915 well suited to such an environment. The number of tracers in CanOE is not particularly large
916 compared with other CMIP6 models. We expect to further refine CanOE and its
917 parameterizations, evaluate it against new and emerging ocean data sets (e.g., GEOTRACES,

918 biogeochemical Argo), and incrementally improve CMOC (which we will maintain for a wide
919 suite of physical-climate experiments for which ocean biogeochemistry is not central to the
920 purpose). For CMIP6, we chose to keep CMOC as close to the CanESM2 version as possible.
921 This strategy allows us to quantify how much of the improvement in model skill is due to the
922 physical circulation, as is illustrated by greater skill with respect to DIC (Figure 8) and alkalinity
923 (Supplementary Figure S4), particularly at intermediate depths (400-900 m). The CanESM
924 terrestrial carbon model is also undergoing important new developments (e.g., Asaadi and Arora,
925 2021) and we expect CanESM to continue to offer a credible contribution to global carbon cycle
926 studies, as well as advancing regional downscaling and impacts science.

927

928 *Code availability.* The full CanESM5 source code is publicly available at
929 gitlab.com/ccma/canesm; within this tree the ocean biogeochemistry code can be found at
930 gitlab.com/ccma/cannemo/-/tree/v5.0.3/nemo/CONFIG/CCC_CANCLP_ORCA1_LIM_CMOC
931 or [CCC_CANCLP_ORCA1_LIM_CANOE](https://gitlab.com/ccma/cannemo/-/tree/v5.0.3/nemo/CONFIG/CCC_CANCLP_ORCA1_LIM_CANOE) (last access: 21 September 2021). The version of the
932 code which can be used to produce all the simulations submitted to CMIP6, and described in this
933 paper, is tagged as v5.0.3 and has the associated DOI: <https://doi.org/10.5281/zenodo.3251113>
934 (Swart et al., 2019b).

935

936 *Data availability.* All simulations conducted for CMIP6, including those described in this paper,
937 are publicly available via the Earth System Grid Federation (source_id = CanESM5 or
938 CanESM5-CanOE). All observational data and other CMIP6 model data used are publicly
939 available.

940

941 *Author contributions.* Formulation of the overall research goals and aims: JRC, KLD, NS, NCS;
942 Implementation and testing of the model code: JRC, HH, AMH, WGL, OGJR, AES, NCS;
943 Carrying out the experiments: JRC, WGL, OGJR, AES, NCS; Creation of the published work:
944 JRC, HH, AMH, AES, NS, NCS.

945

946 *Competing interests.* The authors declare that they have no conflict of interest.

947

948 *Disclaimer.* CanESM has been customized to run on the ECCC high-performance computer, and
949 a significant fraction of the software infrastructure used to run the model is specific to the
950 individual machines and architecture. While we publicly provide the code, we cannot provide
951 any support for migrating the model to different machines or architectures.

952

953 *Acknowledgments.* This work was made possible by the combined efforts of the CCCMa model
954 development team and computing support team. We thank all of the the data contributors to and
955 developers of the observational data products, the NASA ocean colour team, and all of the
956 CMIP6 data contributors. The Python packages mocsy by Jim Orr and SkillMetrics by Peter
957 Rochford were invaluable tools in the analysis. William Merryfield and Andrew Ross made
958 useful comments on an earlier draft. Fiona Davidson helped with figure preparation. This paper
959 is dedicated to the memory of Mr. Fouad Majaess, who supported CCCMa supercomputer users
960 for many years and passed away suddenly in 2020.
