## 11 **Abstract**

12       The effect of the air–sea interaction on the Madden–Julian Oscillation (MJO)  
13 was investigated using the one-column ocean model Snow–Ice–Thermocline (SIT  
14 1.06) embedded in the Community Atmosphere Model 5.3 (CAM5.3; hereafter  
15 CAM5–SIT v1.0). The SIT model with 41 vertical layers was developed to simulate  
16 sea surface temperature (SST) and upper-ocean temperature variations with a high  
17 vertical resolution that resolves the cool skin and diurnal warm layer and the upper  
18 oceanic mixed layer. A series of 30-year sensitivity experiments were conducted in  
19 which various model configurations (e.g., coupled versus uncoupled, vertical  
20 resolution and depth of the SIT model, coupling domains, and absence of the diurnal  
21 cycle) were considered to evaluate the effect of air–sea coupling on MJO simulation.  
22 Most of the CAM5–SIT experiments ~~exhibited~~exhibit higher fidelity than the CAM5-  
23 alone experiment in characterizing the basic features of the MJO such as  
24 spatiotemporal variability and the eastward propagation in boreal winter. The overall  
25 MJO simulation performance of CAM5–SIT ~~benefited~~benefits from (1) better  
26 resolving the fine vertical structure of upper-ocean temperature and therefore the air–  
27 sea interaction that ~~resulted~~result in more realistic intraseasonal variability in both  
28 SST and atmospheric circulation and (2) the adequate thickness ~~and vertical~~  
29 ~~resolution~~ of ~~the oceanic~~ vertically-gridded ocean mixed layer. The sensitivity  
30 experiments ~~demonstrated~~demonstrate the necessity of coupling the tropical eastern  
31 Pacific in addition to the tropical Indian Ocean and the tropical western Pacific.  
32 Coupling is more essential in the south than north of the equator in the tropical  
33 western Pacific. Enhanced MJO could be obtained without considering the diurnal  
34 cycle in coupling.

## 35 1. Introduction

36 The Madden–Julian Oscillation (MJO) is a tropical large-scale convection  
37 circulation system that propagates eastward across the warm pool region from the  
38 tropical Indian Ocean (IO) to the western Pacific (WP) on an intraseasonal time scale  
39 (Madden and Julian, 1972). The MJO is not just an atmospheric phenomenon. The  
40 findings ~~of the multinational joint~~[from a multi-nation](#) field campaign called the  
41 [Dynamics of MJO](#)/Cooperative Indian Ocean Experiment on Intraseasonal Variability  
42 in the Year 2011/~~Dynamics of the MJO~~ ([\(DYNAMO/CINDY2011](#); de Szoeké et al.,  
43 2017; Johnson and Ciesielski, 2017; Pujiana et al., 2018; Yoneyama et al., 2013;  
44 Zhang and Yoneyama, 2017) revealed vigorous air–sea coupling during the evolution  
45 of the MJO (Chang et al., 2019; DeMott et al., 2015; Jiang et al., 2015, 2020; Kim et  
46 al., 2010; Li et al., 2016; Li et al., 2020; Newman et al., 2009; Pei et al., 2018; Tseng  
47 et al., 2014). During the suppression of convection, the MJO propagates eastward  
48 with light winds, which is accompanied by enhanced downwelling shortwave  
49 radiation absorption, weaker upward latent and sensible fluxes, less cloudiness and  
50 precipitation, and weaker vertical mixing in the upper ocean, thus causing an increase  
51 in the upper-ocean temperature. In the following active phase when deep convection  
52 occurs, downwelling shortwave radiation is reduced and stronger westerly winds  
53 enhance ~~evaporation and latent~~/sensible heat [flux \(LHF/SHF\)](#) loss from the ocean  
54 surface, thus causing a decrease in the upper-ocean temperature (DeMott et al., 2015;  
55 Madden and Julian, 1972, 1994; Zhang, 2005).

56 In addition to the ocean surface, the structure of the upper ocean also evolves.  
57 Alappattu et al. (2017) reported that during an MJO event, surface flux perturbations  
58 cause changes in the ocean thermohaline structure, thus affecting the mixed-layer  
59 temperature. The following change in sea surface temperature (SST) can further affect  
60 atmospheric circulation of the MJO. Variations in SST mediate ~~heat~~[LHF and SHF](#)

61 exchange across the air–sea interface. Although SST responds to atmospheric forcing,  
62 ~~itsthe~~ modulation of ~~surface heat fluxes~~LHF and SHF provides feedback to the  
63 atmosphere (DeMott et al., 2015; Jiang et al., 2020). Li et al. (2008, 2020) proposed  
64 that the phase relationship between SST and convection implies a delayed air–sea  
65 interaction mechanism whereby a preceding active-phase MJO may trigger an  
66 inactive-phase MJO through the delayed effect of the induced SST anomaly over the  
67 IO. The reduction in SST caused by a preceding active-phase MJO may, in turn,  
68 ~~yieldyields~~ delayed ocean feedback that initiates a suppressed-phase MJO, and vice  
69 versa. The ~~nonnegligible~~by-no-means negligible effect of intraseasonal SST  
70 variations caused by surface heat fluxes suggests that the ocean state can affect the  
71 MJO (DeMott et al., 2015, 2019; Hong et al., 2017; Li et al., 2020).

72 Since its discovery almost five decades ago, the MJO remains a phenomenon  
73 that poses a challenge to the capacity of state-of-the-art atmospheric general  
74 circulation models (AGCMs) ~~and climate models~~ such as those participating in the  
75 Coupled Model Intercomparison Project phase 5 and 6 to generate successful  
76 simulations (Ahn et al., 2017, 2020; Bui and Maloney 2018; Jiang et al., 2020; Hung  
77 et al., 2013; Kim et al., 2011).

78 Recent studies have reported that air–sea coupling improves the representation of  
79 the MJO in numerical simulation (Bernie et al., 2008; Crueger et al., 2013; DeMott et  
80 al., 2015; Li et al., 2016; Li et al., 2020; Tseng et al., 2014; Woolnough et al., 2007).  
81 Tseng et al. (2014) indicated that effectively resolving the upper-ocean warm layer to  
82 capture temperature variations in the upper few meters of the ocean could improve  
83 MJO simulation. DeMott et al. (2015) suggested that the tropical atmosphere–ocean  
84 interaction may sustain or amplify the pattern of the enhanced and suppressed  
85 atmospheric convection of the eastward propagation. DeMott et al. (2019)  
86 demonstrated that the improved MJO eastward propagation in four coupled models

87 resulted from enhanced low-level convective moistening for a rainfall rate of >5 mm  
88 day<sup>-1</sup> due to air–sea coupling. In addition, numerical experiments have been  
89 performed to investigate the effect of the diurnal cycle on the MJO (Hagos et al.,  
90 2016; Oh et al., 2013), with the results suggesting that the strength and propagation of  
91 the MJO through the Maritime Continent (MC) were enhanced when the diurnal cycle  
92 was ignored.

93 Although previous studies have demonstrated the importance of considering the  
94 air–sea interaction in a numerical model to improve MJO simulation, additional  
95 details regarding model configuration (e.g., vertical resolution, [and](#) depth of the ocean  
96 mixed layer, coupling domain, and absence of the diurnal cycle [in air-sea coupling](#))  
97 have not been systematically explored. Tseng et al. (2014) coupled the one-column  
98 ocean model Snow–Ice–Thermocline (SIT; Tu and Tsuang, 2005) to the fifth  
99 generation of the ECHAM AGCM (ECHAM5–SIT) and indicated that a vertical  
100 resolution of 1 m was essential to yield an improved simulation of the MJO with a  
101 realistic strength and eastward propagation speed.

102 In this study, we coupled the SIT model to the Community Atmosphere Model  
103 version 5.3 (CAM5.3; Neale et al., 2012)—the atmosphere component of the  
104 Community Earth System Model version 1.2.2 (CESM1.2.2; Hurrell et al., 2013)—to  
105 explore [how the air–sea interaction in AGCMs can improve improvement of MJO](#)  
106 [simulation by coupling SIT model to another AGCM is reproducible in modeling](#)  
107 [science](#). The CAM5.3, which has been widely used for the long-term simulation of the  
108 climate system, could not efficiently simulate the eastward propagation of the MJO;  
109 instead, the model simulated a tendency for the MJO to move westward in the IO  
110 (Boyle et al., 2015, Jiang et al, 2015). By contrast, the updated CESM2 with the new  
111 CAM6 could realistically simulate the MJO (Ahn et al., 2020; Danabasoglu et  
112 al., 2020). Thus, the well-explored CAM5, which does not produce a realistic MJO,

113 appears to be a favorable choice for exploring ~~how~~ coupling a simple one-dimensional  
114 (1-D) ocean model, such as the SIT model, can improve MJO simulation, as well as  
115 the effects of model configuration: ~~on the degree of the improvement~~. Such a study  
116 can also enhance our understanding regarding the ~~effect of air-sea coupling's effect~~  
117 on the MJO.

118 ~~This study examined how air-sea coupling can improve MJO simulation,~~  
119 ~~especially that of the eastward propagation that has been poorly simulated in many~~  
120 ~~climate models~~. The MJO that exhibits a more substantial eastward propagation in  
121 boreal winter than in other seasons was the targeted feature in this study. ~~We~~To  
122 examine the sensitivity of MJO simulations to different configurations of air-sea  
123 coupling, we conducted a series of 30-year numerical experiments by considering  
124 various model configurations (e.g., coupled versus uncoupled, vertical resolution and  
125 depth of the SIT model, coupling domains, and absence of the diurnal cycle) to  
126 investigate the effect of air-sea coupling. This paper is organized as follows. Section  
127 2 describes the data, ~~methodology for validation, the model used for simulation, and~~  
128 ~~model setup~~. ~~Section 3 presents the~~ the design of ~~coupled model~~ numerical  
129 experiments. Section ~~4~~ 3 describes the effect of various ~~model~~ air-sea coupling  
130 configurations on the MJO simulation determined through detailed MJO diagnostics.  
131 ~~A discussion~~ Discussion and conclusions are provided in Section ~~5~~ 4.

## 133 ~~2.~~ 2. Data, methodology, and model description, and experimental designs

### 134 ~~2.1~~ 2.1 Observational data and analysis methods

#### 135 2.1 Data and methodology

136 The data analyzed in this study include precipitation from the Global  
137 Precipitation Climatology Project, (GPCP), outgoing longwave radiation (OLR) and  
138 daily SST (Optimum Interpolation SST; OISST) from the National Oceanic and

139 Atmosphere Administration (NOAA), and parameters from the ERA-Interim ([ERA-I](#))  
140 reanalysis (Adler et al., 2003; Dee et al., 2011; Lee et al., 2011; Reynolds and Smith,  
141 1995; Schreck et al., 2018). The ~~initial~~ SST data for the SIT model were obtained  
142 from the Hadley Centre Sea Ice and Sea Surface Temperature dataset (Rayner et al.,  
143 2003; [HadISST1](#)) and the ocean subsurface data (40-layer climatological ocean  
144 temperature, salinity, and currents) for nudging were retrieved from the National  
145 Centers for Environmental Prediction (NCEP) Global Ocean Data Assimilation  
146 System (GODAS; Behringer and Xue, 2004). ~~Ocean bathymetry was derived from the~~  
147 ~~NOAA ETOPO1 data (Amante and Eakins, 2009) and interpolated into 1.9° × 2.5°~~  
148 ~~horizontal resolution.~~

149 We used the CLIVAR MJO Working Group diagnostics package (CLIVAR,  
150 2009) and a 20–100-day filter (Kaylor, 1977; Wang et al., 2014) to determine  
151 intraseasonal variability. MJO phases were defined following the index (namely,  
152 RMM1 and RMM2) proposed by Wheeler and Hendon (2004), which considers the  
153 first two principal components of the combined near-equatorial OLR and zonal winds  
154 at 850 and 200 hPa. The band-passed filtered data were used for calculating the index  
155 and defining phases.

156

## 157 **2.2 Model description**

### 158 **2.2.1 CAM5.3**

159 The CAM5.3 used in this study has a horizontal resolution of 1.9° latitude ×  
160 2.5° longitude and 30 vertical levels with the model top at 0.1 hPa. The MJO could  
161 not be realistically simulated in the CAM5.3. Boyle et al. (2015) demonstrated that  
162 although making the deep convection dependent on SST improved the simulation of  
163 the MJO variance, it exerted a significant negative effect on the mean-state climate of  
164 low-level cloud and absorbed shortwave radiation. By comparing the simulation

165 results of an uncoupled and coupled CAM5.3, Li et al. (2016) suggested that air–sea  
 166 coupling and the convection scheme most significantly affected the MJO simulation  
 167 in the climate model.

168

### 169 2.2.2 1-D high-resolution TKE ocean model

170 The 1-D high-resolution turbulence kinetic energy (TKE) ocean model SIT was  
 171 used to simulate the diurnal fluctuation of SST and surface energy fluxes. (Lan et  
 172 al., 2010; Tseng et al., 2014; Tu and Tsuang, 2005). The model was well verified  
 173 against ~~surface and subsurface observations in~~ in situ measurements on board the R/V  
 174 Oceanographic Research Vessel 1 and 3 over the South China Sea (Lan et al., 2010)  
 175 and on R/V Vickers over the tropical WP (Tu and Tsuang, 2005). ~~Variations in sea-~~  
 176 ~~water temperature ( $T$ ), current ( $\vec{u}$ ), and salinity ( $S$ ) were determined (Gaspar et al.,~~  
 177 ~~1990) using the following equations.~~

$$178 \quad \frac{\partial T}{\partial t} = (k_h + v_h) \frac{\partial^2 T}{\partial z^2} + \frac{R_{s\pi}}{\rho_{w0} c_w} \frac{\partial F}{\partial z} \quad (1)$$

$$179 \quad \frac{\partial \vec{u}}{\partial t} = -f \hat{k} \times \vec{u} + (k_m + v_m) \frac{\partial^2 \vec{u}}{\partial z^2} \quad (2)$$

$$180 \quad \frac{\partial S}{\partial t} = (k_h + v_h) \frac{\partial^2 S}{\partial z^2} \quad (3)$$

181 where  $R_{s\pi}$  is the net solar radiation at the surface ( $\text{W m}^{-2}$ ),  $F(z)$  is the fraction  
 182 (dimensionless) of  $R_{s\pi}$  that penetrates to the depth  $z$ , and  $k_h$  and  $k_m$  are eddy diffusion  
 183 coefficients for heat and momentum ( $\text{m}^2 \text{s}^{-1}$ ), respectively. The value of  $k_h$  within the  
 184 cool skin layer and that of  $k_m$  within the viscous layer were set to zero. Molecular  
 185 transport is the only mechanism for the vertical diffusion of heat and momentum in  
 186 the cool skin and viscous layer, respectively (Hasse, 1971; Grassl, 1976; Wu,  
 187 1985). The parameters  $v_m$  and  $v_h$  are the molecular diffusion coefficients for  
 188 momentum and temperature, respectively,  $\rho_{w0}$  is the density ( $\text{kg m}^{-3}$ ) of water, and  
 189  $c_w$  is the specific heat capacity at constant pressure ( $\text{J kg}^{-1} \text{K}^{-1}$ ).  $S$  is salinity (‰),  $\vec{u}$

190 is the current velocity ( $\text{m s}^{-1}$ ),  $f$  is the Coriolis parameter (dimensionless), and  $\hat{k}$  is  
 191 the vertical unit vector ( $\text{m s}^{-1}$ ).

192 The eddy diffusivity for momentum  $k_m$  is simulated using an eddy kinetic energy  
 193 approach based on the Prandtl–Kolmogorov hypothesis as follows:

$$194 \quad k_m = c_k l_k \sqrt{E} \quad (3)$$

195 where  $c_k = 0.1$  (Gaspar et al., 1990),  $l_k$  is the mixing length (m), and  
 196  $E = 0.5(u'^2 + v'^2 + w'^2)$  is turbulent kinetic energy. The turbulent kinetic energy ( $E$ )  
 197 is determined using a 1-D equation (Mellor and Yamada, 1982) as follows:

$$198 \quad \frac{\partial E}{\partial t} = \frac{\partial}{\partial z} k_m \frac{\partial E}{\partial z} + k_m \left( \frac{\partial \bar{u}}{\partial z} \right)^2 + k_h \frac{g}{\rho_w} \frac{\partial \rho_w}{\partial z} - c_\varepsilon \frac{E^{3/2}}{l_\varepsilon} \quad (4)$$

199 where  $c_\varepsilon = 0.7$  (Gaspar et al., 1990),  $g$  is the gravity ( $\text{m s}^{-2}$ ),  $\rho_w$  is the density of  
 200 water ( $\text{kg m}^{-3}$ ), and  $l_\varepsilon$  is the characteristic dissipation length (m). The mixing length  
 201 ( $l_k$ ) and dissipation length ( $l_\varepsilon$ ) were determined following the approach reported by  
 202 Gaspar et al. (1990). This approach is valid for determining the eddy diffusivity of  
 203 both the ocean mixed layer and surface layer.

204 In the SIT model setting, the specific heat of sea water is a constant ( $4186.84 \text{ J}$   
 205  $\text{kg}^{-1} \text{ K}^{-1}$ ), and the Prandtl number in water is defined as the ratio of momentum  
 206 diffusivity to thermal diffusivity, which is a dimensionless number set as a constant  
 207 (1.0). The kinematic viscosity is a constant ( $1.14 \times 10^{-6} \text{ m}^2 \text{ s}^{-1}$ ; Paulson and  
 208 Simpson, 1981), and the downward solar radiative flux into water with nine  
 209 wavelength bands was determined following the approach reported by Paulson and  
 210 Simpson (1981). The minimum turbulent kinetic energy is set to  $10^{-6} \text{ m}^2 \text{ s}^{-2}$ , and the  
 211 zero displacement is set to 0.03 m.

212 The SIT model determines the vertical profiles of the temperature and

213 momentum of a water column from the surface down to the seabed, except in the  
214 fixed ocean model bottom experiment. The default setting of vertical discretization  
215 (e.g., in the control coupled experiment) is 41 layers with 12 layers in the first 10.5 m,  
216 6 layers between 10.5 m and 107.8 m (Supplementary Information I). In the 1-D TKE  
217 ocean model, temperature and salinity below 107.8 m, where vertical mixing is  
218 greatly weakened, are nudged toward the climatological values of GODAS data until  
219 4607 m. The extra high vertical resolution is needed to catch detailed temporal  
220 variation of upper ocean temperature characterized by the warm layer and cool skin  
221 (Tu and Tsuang, 2005). To account for the neglected horizontal advection heat flux,  
222 the ocean is weakly nudged (by using a 30-day time scale) between 10.5 m and  
223 ~~100~~107.8 m and strongly nudged (by using a 1-day time scale) below ~~100~~107.8 m  
224 according to the NCEP GODAS climatological ocean temperature; ~~no~~. No nudging is  
225 performed ~~for depths under 10 m. Considerably fine 41-layer vertical discretization is~~  
226 ~~applied, with 12 layers in~~within the upper-most 10.5 m. ~~The resolution in the upper 10~~  
227 ~~m is considerably fine to capture the upper-ocean warm layer, and the thickness of the~~  
228 ~~first layer below sea surface is 0.05 mm to reproduce the ocean surface cool skin. The~~  
229 ~~41 levels are at the surface and at the depths of 0.05 mm, 1.0 cm, 2.0 cm, 3.0 cm, 4.0~~  
230 ~~cm, 5.0 cm, 6.0 cm, 7.0 cm, 8.0 cm, 9.0 cm, 10.0 cm, 16.8 cm, 29.5 cm, 43.6 cm, 59.2~~  
231 ~~cm, 76.9 cm, 96.8 m, 119.4 cm, 145.3 cm, 174.9 cm, 208.9 m, 248.3 cm, 293.8 cm,~~  
232 ~~346.8 cm, 408.4 cm, 480.2 cm, 564.3 cm, 662.6 cm, 777.9 cm, 913.1 cm, 1072.0 cm,~~  
233 ~~1258.8 cm, 1478.6 cm, 1737.3 cm, 2042.0 cm, 2401.1 cm, 2824.4 cm, 3323.6 cm,~~  
234 ~~3912.4 cm, and 4607.1 cm.~~ The SIT model calculates data two timesttwice for each  
235 CAM5 time step (30 min; i.e., coupling 48 times per day).

236

### 237 2.3. Experimental setup design

238 Five setsA series of 30-year numerical experiments (Table 1) were conducted to

239 investigate the effect of the air–sea interaction on the MJO simulation. ~~In all~~  
240 ~~simulations,~~The HadSST1 used to force the CAM5.3-coupled and uncoupled model  
241 was ~~forced by observed~~the climatological monthly-SST ~~except~~-mean SST averaged  
242 ~~over 1982-2001. The monthly SST was linearly interpolated to daily SST fluctuation~~  
243 ~~that forced the model. The SST in the~~air–sea coupling region ~~where the SIT model~~  
244 ~~determined the upper ocean temperature. The~~ was recalculated by the SIT during the  
245 ~~simulation, while the prescribed annual cycle of SST was used in the areas outside the~~  
246 ~~coupling region. Ocean bathymetry of the SIT was derived from the NOAA ETOPO1~~  
247 ~~data (Amante and Eakins, 2009) and interpolated into 1.9° × 2.5° horizontal~~  
248 ~~resolution.~~

249 All simulations were driven by the prescribed annual cycle of SST repeatedly for  
250 30 years. The strategy is to evaluate the simulation capacity of climate models under  
251 the same condition without considering interannual variation induced by SST. This  
252 approach has been widely adopted in many studies (Delworth et al., 2006; Haertel et  
253 al., 2020; Subramanian et al., 2011; Tseng et al., 2014; Wang et al., 2005).

254 Atmospheric initial conditions and external forcing such as CO<sub>2</sub>, ozone, and  
255 aerosol in near-equilibrium climate state around the year 2000 were taken from  
256 F\_2000\_CAM5 component set based on CESM1.2.2 framework development. The  
257 data has been commonly used in present-day simulations using CAM5 (e.g., He et al.,  
258 2017).

259 The setup of five sets of experiment sets were conducted in this study are  
260 described as follows.

261 (1) a standalone CAM5.3 simulation forced by ~~observed~~climatological monthly  
262 SSTHadISST1 (A–CTL) and athe control experiment of coupled CAM5–SIT–  
263 v1.0 simulation (C–30NS; 41 vertical levels, coupling in the entire tropics  
264 between 30°SN and 30°NS with a diurnal cycle);).

265 (2) ~~an upper~~Upper-ocean vertical resolution experiment (C-LR12m and C-LR34m):  
 266 ~~two coarse vertical resolution simulations with a thickness of 11.8 and 34.2 m,~~  
 267 ~~respectively, at the third layer;~~ (3) a lower-ocean boundary experiment: three ~~Two~~  
 268 simulations with the ~~lower boundary of the SIT model~~first layer centering at 12  
 269 m (C-LR12m) and 34 m (C-LR34m). Further details of the experimental design  
 270 are shown in supplementary Fig. S1.

271 (3) Shallow ocean bottom experiment: Three simulations with the ocean model  
 272 ~~bottom~~ at 10 m (C-HR1mB10m), 30 m (C-HR1mB30m), and 60 m (C-  
 273 HR1mB60m)}; ~~);~~ (supplementary Fig. S2).

274 (4) ~~a regional~~Regional coupling experiment: ~~Four~~ simulations with ~~four~~the coupling  
 275 ~~domains, namely the latitudinal effect [region in 0°N–30°N (C-0\_30N) and 0°S–~~  
 276 ~~30°S (C-0\_30S)] and the longitudinal) for latitudinal effect [, and 30°E–180°E~~  
 277 ~~(C-30\_180E) and 30°E–75°W (C-30E\_75W)] (see the) for longitudinal effect.~~  
 278 ~~The coupling domain~~domains are shown in Fig. 1); ~~and~~.

279 (5) ~~a~~A non-diurnal coupling experiment: ~~a nondiurnal~~ simulation (C-30NS-nD) that  
 280 considers the air-sea interaction ~~by only once a day, namely,~~ calculating ~~ocean-~~  
 281 ~~surface fluxes SHF and LHF~~ based on daily mean atmospheric variables and SST  
 282 (C-30NS-nD), ~~with~~. To prevent the inconsistent local time in different regions,  
 283 the coupling frequency ~~maintained~~at each grid point remained 48 times per day  
 284 ~~to prevent the local time in different regions from being inconsistent when-~~  
 285 ~~coupling once a day. Greenhouse gas concentrations were fixed at the using the~~  
 286 ~~same daily means of atmospheric variables and SST at that particular point. In~~  
 287 ~~contrast, the control simulation calculates air-sea fluxes 48 times a day based on~~  
 288 ~~instantons~~ values ~~observed in the year 2000. A comparison between the non-~~  
 289 ~~diurnal simulation and the control simulation reveals the effect of diurnal cycle~~  
 290 ~~in air~~sea coupling.

291 ~~The main codes of the SIT model in Fortran 90 are packaging in independent~~  
292 ~~and original subprograms, with data and interface blocks in modules, that creates~~  
293 ~~explicit interfaces between the CAM5.3 and the SIT model without a coupler. In~~  
294 ~~addition, these modules contain dynamically allocable arrays and the independent I/O~~  
295 ~~procedures of the SIT model. The coupler in the CAM5-SIT only brokers~~  
296 ~~communication interchanges between the simulated SST and calculated oceanic~~  
297 ~~surface fluxes.~~

299 4

### 300 **3. Results and Discussion**

301 The realistic simulation of the MJO has always been a major bottleneck in the  
302 development of climate models. In this section, we demonstrate ~~how~~the sensitivity of  
303 air-sea coupling experiments using a 1-D high-resolution ocean ~~mixed-layer~~ model  
304 significantly improves the MJO simulation by the CAM5.3. The period between  
305 November and April when the MJO is the most prominent was the targeted season in  
306 this study.

#### 308 **4.3.1 Improvement of MJO simulation through air-sea coupling**

309 This subsection compares the MJO simulation of the control coupled  
310 ~~model~~experiment (C-30NS) with that of the uncoupled AGCM (A-CTL) forced by  
311 climatological monthly SST of HadISST1 to demonstrate the effect of air-sea  
312 coupling on the MJO simulation by coupling the SIT model to the CAM5.3 in the  
313 tropical belt (30°N-30°S).

##### 315 **4.3.1.1 Wavenumber-frequency spectra and eastward propagation characteristics**

316 A wavenumber-frequency spectrum (W-FS) analysis was conducted to quantify

317 propagation characteristics simulated in different experiments. The spectra  
318 of unfiltered U850 in ~~observation~~ERA-I reanalysis, C-30NS, and A-CTL are shown  
319 in Fig. 2a-c, respectively. The ~~coupled~~C-30NS ~~effectively simulated~~considering the  
320 ~~observed~~coupling in 30°N-30°S realistically simulates eastward-propagating signals  
321 at zonal wavenumber 1 and 30-80-day periods (Fig. 2a-b), although with a slightly  
322 larger amplitude. compared with ERA-I. By contrast, the uncoupled A-CTL ~~did~~does  
323 not ~~effectively simulate the observed characteristics~~yield realistic simulation; instead,  
324 it ~~simulated~~simulates both eastward (wavenumber 1)- and westward (wavenumber 2)-  
325 propagating signals with an unrealistic spectral shift to time scales longer than ~~the~~  
326 ~~observed~~ 30-80-day period.

327 The major features of the simulated MJO propagation were examined. Figure  
328 2d-f show the time evolution of ~~intraseasonal~~ precipitation and U850 anomalies in  
329 Hovmöller diagrams; specifically, which represent lagged correlation coefficients  
330 between the precipitation ~~at~~averaged over 10°S-5°N, 75-100°E ~~with~~and the ~~average~~  
331 precipitation ~~at~~and U850 averaged over 10°N-10°S ~~and U850 anomalies along the~~  
332 ~~equator~~on intraseasonal timescales. Figure 2d indicates eastward propagation for both  
333 precipitation and U850 from the eastern IO to the dateline, with precipitation leading  
334 U850 by approximately a quarter of a cycle. The Hovmöller diagram derived from the  
335 C-30NS (Fig. 2e) exhibits the key characteristics of eastward propagation for both  
336 precipitation and U850 and the relative phases between the two, although the  
337 simulated correlation ~~was~~is slightly weaker than that ~~observed~~derived from GPCP  
338 and ERA-I. By contrast, the uncoupled A-CTL ~~simulated~~simulates intraseasonal  
339 signals that ~~propagated~~propagate westward over the IO and ~~simulated~~ weak and much  
340 slower eastward propagation crossing the MC and WP (Fig. 2f). The contrast between  
341 Fig. 2e and 2f ~~demonstrated~~demonstrate that coupling a 1-D-~~ocean~~ TKE ocean model  
342 alone could lead to a significant improvement in an AGCM in simulating the major

343 characteristics (e.g., amplitude, propagation direction and speed, and phase  
344 relationship between precipitation and circulation) of the MJO.

345

### 346 **4.1.2 Coherence of the simulated MJO**

347 Cross-spectral analysis was ~~performed~~conducted to examine the coherence and  
348 phase lag between tropical circulation and convection, which were plotted over the  
349 tropical wave spectra. Figure 2g–i show the symmetric part (e.g., Wheeler and  
350 Kiladis, 1999) of OLR and U850 in ~~observation~~ERA-I/NOAA data, C-30NS, and A-  
351 CTL, respectively. We present only ~~a magnified display of the~~ spectra between ~~the~~  
352 ~~frequency of~~ 0 to  $0.35 \text{ day}^{-1}$  to highlight the MJO and equatorial Kelvin waves. The  
353 most prominent ~~characteristic observed was~~characteristics seen in ERA-I/NOAA data  
354 are the peak coherence at wavenumbers 1–3 and a phase lag of approximately  $90^\circ$  in  
355 the 30–80-day band ~~for the symmetric component associated with the MJO~~ (Ren et  
356 al., 2019; Wheeler and Kiladis 1999). The coupled experiment C-30NS  
357 ~~simulated~~simulates strong coherence in this low-frequency band (wavenumber 1) and  
358 ~~exhibited~~exhibits a realistic phase lag relationship between U850 and OLR  
359 perturbations. However, the coherence at wavenumbers 2–3 for the 30–80-day period  
360 simulated by C-30NS ~~was~~is weaker than that ~~observed. In addition, this in ERA-~~  
361 I/NOAA data. This undersimulation was also noted in CCSM4 (Subramanian et al.,  
362 2011), the uncoupled and coupled CAM4 and CAM5 (Li et al., 2016), and NorESM1-  
363 M (Bentsen et al., 2013), which had a version of the CAM as an AGCM. In summary,  
364 C-30NS ~~produced~~considering the coupling between 30°N–30°S produces coherent  
365 and energetic patterns in the eastward-propagating intraseasonal fluctuations of U850  
366 and OLR in the tropical IO and WP that are generally consistent with the MJO  
367 characteristics. By contrast, the MJO characteristics in A-CTL ~~were~~are considerably  
368 weaker than those in C-30NS and that ~~observed in~~ ERA-I/NOAA data.

369

### 370 **43.1.3 Horizontal and vertical structures of the MJO across the MC**

371 Figure 2j–o show the horizontal and vertical structures of the MJO when deep  
372 convection is the strongest over the MC (i.e., phase 5). Figure 2j–l present the 20–  
373 100-day filtered OLR ( $\text{W m}^{-2}$ , shaded) and 850-hPa wind ( $\text{m s}^{-1}$ , vector). C–30NS  
374 realistically simulated the enhanced tropical convection over the eastern IO and the  
375 Kelvin-wave-like easterly anomalies over the tropical WP despite undersimulating  
376 the convection over the MC (Fig. 2j and 2k). By contrast, A–CTL failed to simulate  
377 the enhanced convection over the eastern IO and MC; instead, it simulated  
378 considerably weaker convection and easterly winds over the MC and WP,  
379 respectively, than that [observed in ERA-I/NOAA data](#) (Fig. 2j and 2l).

380 Figure 2m–o show the vertical–longitudinal profiles of 20–100-day filtered  
381  $15^{\circ}\text{N}$ – $15^{\circ}\text{S}$  averaged vertical velocity (OMEGA;  $\text{Pa s}^{-1}$ , shaded) and moist static  
382 energy (MSE) anomalies ( $\text{W m}^{-2}$ , contour) at phase 5. The spatial distribution of  
383 negative OMEGA (ascending motion) anomalies generally agreed with OLR  
384 anomalies in C–30NS simulation and [observation/NOAA data](#) over the Indo-Pacific  
385 region (Fig. 2m and 2n). The [observed relatively](#) spatial relationship between  
386 the ascending motion and MSE [was seen in ERA-I](#) is well simulated in [the coupled](#)  
387 [experiment](#) C–30NS. For example, positive MSE anomalies on the eastern side of the  
388 anomalous ascent [demonstrated/demonstrate](#) that the energy recharge process occurs in  
389 advance of the MJO convection over the lower-tropospheric easterlies (Fig. [2j/2m](#) and  
390 [2k/2n](#)), whereas negative MSE anomalies on the western side [revealed/reveal](#) that the  
391 discharge process occurs during and after convection over the lower-tropospheric  
392 westerlies. By contrast, this phase relationship, considered to be an essential feature  
393 leading to the eastward propagation of an MJO (Hannah and Maloney 2014; Heath et  
394 al., 2021), [was/is](#) not properly simulated in [the uncoupled experiment](#) A–CTL (Fig.

395 2o), in which the simulated weak negative OMEGA ~~wasis~~ located between negative  
396 and positive MSE anomalies over weak lower-tropospheric wind anomalies and  
397 associated with weak convection over the MC (Fig. 2l).

398 The ~~observed~~-temporal evolution [of NOAA OLR and ERA-I U850](#) (Fig. 3a)  
399 ~~indicated~~[indicates](#) that convection originating in the western IO ~~wasis~~ enhanced  
400 during its eastward propagation to the MC where it ~~reached~~[reaches](#) the peak  
401 amplitude and then gradually weakened when continuing moving eastward to the  
402 dateline. ~~In the coupled experiment~~ C-30NS, this evolution of convectively  
403 coupled circulation ~~wasis~~ realistically simulated, although it ~~wasis~~ weaker than the  
404 ~~observed~~-strength [seen in NOAA OLR](#) (Fig. 3b). Moreover, the split of convection  
405 into two cells off the equator in phase 6 ~~wasis~~ appropriately simulated in C-30NS  
406 (P6 in Fig. 3a and 3b). This split was caused by the topographic and land-sea  
407 contrast effects of the MC (Tseng et al., 2017). Associated with the split ~~wasis~~ the  
408 southward detouring of the anomalous convection during the passage of the MJO  
409 through the MC (Kim et al. 2017, Tseng et al., 2017; Wu and Hsu, 2009). After the  
410 passage of the MJO through the MC, the anomalous convection ~~stayed~~[stays](#) south of  
411 the equator and ~~continued~~[continues](#) moving eastward to the dateline. In the  
412 uncoupled A-CTL, the systematic eastward propagation of convectively coupled MJO  
413 circulation from the IO into the MC ~~wasis~~ not simulated. Instead, the convection over  
414 the MC ~~developed~~[develops](#) in situ at a later stage than that observed (e.g., P6 in Fig.  
415 3c) and dissipated rapidly. The A-CTL ~~simulated~~[simulates](#) a pair of off-equator  
416 convection anomalies in the eastern IO during phase 2 (P2 in Fig. 3c) that  
417 ~~moved~~[moves](#) westward toward the central IO and were amplified at later stages (e.g.,  
418 P4 in Fig. 3c). This unrealistic evolution explains the westward propagation tendency  
419 observed in the Hovmöller diagram (Fig. 2f).

420

#### 421 **43.1.4 Characteristics of air–sea interaction**

422 Figure 4a–c show the longitude–phase diagram in which the 20–100-day filtered  
423 precipitation (shaded) and SST (contour) anomalies were averaged over 10°S–10°N to  
424 determine the relationship between precipitation and SST fluctuations and to establish  
425 a link between air–sea coupling and convection. The propagation of the enhanced  
426 convection with positive SST anomalies to the east could be clearly seen in  
427 [observation GPCP/OISST](#) and [the coupled experiment C–30NS](#) (Fig. 4a and 4b). The  
428 highest SST anomaly (SSTA) [led](#) [leads](#) the maximum precipitation anomaly by  
429 approximately 2–3 phases, and the SSTA [began](#) [begins](#) to decrease following the onset  
430 of enhanced precipitation. The [observation revealed ERA-I and OISST data reveal](#) the  
431 following relationship between [net](#) surface flux and SST: the decreased (increased)  
432 [latent/sensible heat fluxes LHF/SHF](#) and increased (decreased) downward radiation  
433 flux leading (lagging) the positive (negative) SSTA east (west) of anomalous deep  
434 convection. This well-known lead–lag relationship reflecting the active air–sea  
435 interaction in an MJO [was](#) [is](#) realistically simulated in [the coupled experiment C–](#)  
436 [30NS](#) (not shown).

437 The contrast between C–30NS and A–CTL confirms the key role of the air–sea  
438 interaction in contributing to the eastward propagation and demonstrates that the  
439 eastward propagation simulation can be markedly improved by incorporating the air–  
440 sea interaction process in the model, even when using a simple 1-D ocean model such  
441 as SIT.

#### 443 **43.1.5 Vertically tilting structure**

444 The warm SST was the key forcing that contributed to the boundary layer  
445 convergence before the onset of deep convection (Li et al., 2020; Tseng et al., 2014).  
446 Hence, the warmer upper ocean enhances the low-level atmospheric convergence and

447 then leads to enhanced low-level moisture and preconditioned deep convection and  
448 eastward propagation. This moistening process associated with warm ocean surface  
449 temperature ~~wasis~~ well simulated in [the coupled experiment C-30NS](#) but is not shown  
450 here. Instead, we present the coupling of moisture divergence (MD) and [atmospheric](#)  
451 circulation.

452 MD and zonal wind anomalies from the surface to the upper troposphere  
453 averaged over the 10°S–10°N and 120–150°E region are shown in Fig. 4d–f to depict  
454 the relationship between the vertically tilting structure of MD and zonal wind  
455 anomalies. Note that the active convection occurred around phase 5. The coupled  
456 experiment C-30NS (Fig. 4e) realistically ~~simulated~~[simulates](#) the ~~observed~~  
457 deepening of coupled MD and zonal wind anomalies with time (Fig. 4d). An  
458 evolution from the right to left seen in each panel of Fig. 4d–f ~~wasis~~ equivalent to  
459 the eastward movement of vertically tilting circulation from the eastern IO into the  
460 MC because of the eastward-propagating nature of the MJO. Figure 4d and 4e show  
461 that in both ~~observation and~~[ERA-I reanalysis and the coupled experiment C-30NS](#),  
462 the near-surface convergence (negative MD) occurring in the easterly anomalies  
463 ~~led~~[lead](#) the convection and continued deepening up to 500 hPa from phase 2 to  
464 phase 6 when the easterly anomalies ~~switched~~[switch](#) to westerly anomalies. By  
465 contrast, this ~~observed~~ evolution of coupled MD–zonal wind anomalies ~~were~~[are](#) not  
466 appropriately simulated in the uncoupled experiment (Fig. 4f). For example, a slow  
467 deepening with time ~~wasis~~ observed in the MD anomaly but not in the zonal wind  
468 anomaly that ~~exhibited~~[exhibits](#) a vertically decayed structure, suggesting that MD  
469 and wind anomalies ~~were~~[are](#) not well coupled, as noted in ~~observation~~[the ERA-](#)  
470 [I/NOAA data](#) and the [control](#) coupled experiment.

471 In ~~observation~~[the ERA-I reanalysis data](#), the negative near-surface MD  
472 anomalies ~~appeared~~[appear](#) first under the easterly anomaly and ~~continued~~[continue](#)

473 deepening between the easterly and westerly anomalies. This development in the  
474 phase relationship between MD and zonal wind anomalies in both [observation](#)[ERA-](#)  
475 [I reanalysis data](#) and [the](#) coupled simulation is consistent with the well-known  
476 structure embedded in the MJO, namely the near-surface convergence in the easterly  
477 phase (i.e., a boundary-layer moistening process; Kiranmayi and Maloney 2011; Li  
478 et al., 2020; Tseng et al., 2014), followed by the deep convection when transitioning  
479 to the westerly phase. This close phase relationship that is key to the eastward  
480 propagation [was](#) appropriately simulated in the coupled experiment but not in the  
481 uncoupled experiment.

482

#### 483 **43.1.6 Intraseasonal variance of precipitation**

484 Figure 4g–i present the spatial distribution of intraseasonal variance of  
485 precipitation. In [observation](#)[the GPCP data](#), the maximum variance [was](#) noted over  
486 the tropical eastern IO, MC, and tropical WP. The maximum variance south of the  
487 island in the MC and the equator in the tropical WP reflects the southward shift of the  
488 MJO deep convection when passing through the MC, partly due to the blocking effect  
489 of mountainous islands and the higher moisture content over high SST south of the  
490 equator in the region during boreal winter (Kim et al., 2017; Ling et al., 2019; Sobel  
491 et al., 2008; Tseng et al., 2017; Wu and Hsu, 2009). Although the [control](#) coupled  
492 experiment [failed](#)[fails](#) to simulate the variance maximum in the tropical eastern IO, it  
493 appropriately [simulated](#)[simulates](#) the maximum variance over the tropical WP,  
494 reflecting its ability to simulate the eastward propagation of the MJO through the MC.  
495 By contrast, the uncoupled A–CTL experiment [simulated](#)[simulates](#) considerably  
496 weaker intraseasonal variance in both the tropical eastern IO and the tropical WP.  
497 Figure 4j–l are the 20–100-day filtered SST (K, shaded) and 850-hPa wind ( $\text{m s}^{-1}$ ,  
498 vector) during MJO phase 7 when deep convection is the strongest over the dateline.

499 The [coupled experiment](#) C-30NS realistically ~~simulated~~[simulates](#) the negative SST  
500 anomaly over the MC and WP when enhanced tropical convection passed through  
501 the MC to the dateline, indicating the capability of the SIT model to reproduce the  
502 ~~observed~~SST anomaly by exchanging [surface fluxes](#)[LHF/SHF](#) between the  
503 atmosphere and ocean. In A-CTL, no SST anomaly ~~was~~[is](#) evident because the model  
504 was forced by prescribed climatological SST. The contrast seen in Fig. 4j-l  
505 demonstrates the essential role of atmosphere-ocean coupling in shaping the MJO.  
506 A delayed air-sea interaction mechanism was noted, where a preceding active-phase  
507 MJO may trigger an inactive-phase MJO through the delayed effect of the induced  
508 SST anomaly. In addition, the westerly winds at 850 hPa moving southward between  
509 MC and WP ~~were~~[are](#) captured by [the control experiment](#) C-30NS and ~~were~~[are](#)  
510 similar to the ~~observed~~[ERA-I reanalysis](#) winds (Fig. 4j and 4k). By contrast, A-CTL  
511 forced by climatological monthly SST ( $<0.05$  K phase<sup>-1</sup> anomaly) ~~failed~~[fails](#) to  
512 simulate the southward westerly wind of the region extending from the MC to the  
513 dateline (Fig. 4l).

514

#### 515 **[4.23.2](#) Effect of upper-ocean vertical resolution**

516 In the [control](#) coupled [experiment](#) C-30NS, the vertical resolution in the upper  
517 [10.5](#) m was 1 m. Tseng et al. (2014) suggested that fine vertical resolution is crucial  
518 for appropriately simulating the eastward propagation. To investigate the effect of  
519 vertical resolution, two ~~coarse-resolution~~ experiments [with a thicker first layer](#) were  
520 conducted, ~~which involved increasing by moving the~~ [thickness](#)[center](#) of the [first ocean](#)  
521 [layer \(under the cool skin layer\)](#) to [11.85](#) m (C-LR12m) and [34.233.9](#) m (C-LR34m),  
522 respectively, ~~as opposed to the control experiment in which 10 layers were~~  
523 [implemented in the first 10.5 meters \(see supplementary Fig. S1 for vertical](#)  
524 [discretization\)](#). The W-FS spectral peaks of U850 in C-LR12m ~~were~~[are](#) concentrated

525 in eastward-propagating wavenumber 1 at three timescales (e.g., longer than 80 days,  
526 30–80 days, and approximately 30 days; Fig. 5a). In C–LR34m, both eastward and  
527 westward signals ~~were~~are simulated with the dominant W–FS timescale ~~that was~~  
528 longer than 80 days (Fig. 5b). The appearance of both eastward and westward signals  
529 at a lower frequency implied a stronger stationary tendency or weaker eastward-  
530 propagating tendency. This result is consistent with that reported by Tseng et al.  
531 (2014) that the [scientific reproducibility of coarser](#) ~~the~~ resolution ~~is,~~ [the causes a](#)  
532 [longer intraseasonal periodicity and](#) slower ~~is the~~ eastward propagation of the MJO.

533 The effect of vertical resolution on the MJO simulation can be seen in the  
534 Hovmöller diagram. The eastward propagation simulated in C–LR12m (Fig. 5c)  
535 markedly weakened after crossing the MC ~~compared~~compare with that simulated in  
536 [the control experiment C–30NS](#). (Fig. 2e). In C–LR34m, the quasi-stationary  
537 fluctuation and westward propagation ~~were~~are simulated over the IO (Fig. 5d),  
538 appearing similar to those in A–CTL. (Fig. 2f). The ~~observed~~ lead–lag relationship  
539 between precipitation (zonal wind) and SST ~~was~~is poorly simulated in C–LR12m  
540 (Fig. 5e) and even more poorly simulated in C–LR34m (Fig. 5f). This result confirms  
541 the finding reported by Tseng et al. (2014) that a higher vertical resolution in the  
542 [first upper](#) few meters [below the surface](#) allows for a faster air–sea interaction, thus  
543 resulting in a more realistic simulation of the MJO.

544

### 545 **4.3 Effect of the lowest boundary of the SIT model**

546 The ocean is a vital energy source for the MJO. Although vertical resolution is  
547 crucial for the efficiency of air–sea interaction, the thickness of the upper ocean that  
548 interacts with the atmosphere represents the [ocean](#) heat content to substantiate the  
549 MJO. A key question is how thick ~~an oceanic~~ [a vertically-gridded ocean](#) mixed layer  
550 should be for a realistic simulation. To explore this issue, three experiments with a

551 model ocean with a 1-m vertical resolution and the ocean [model \(SIT\)](#) bottom at 10,  
552 30, and 60 m, which included the top ~~11, 13~~ [12, 14](#), and ~~15~~ [16](#) levels, respectively, as  
553 ~~listed~~ [shown in Section 2 supplementary Fig. S2 and Table 1](#), were conducted. The  
554 spectra and the Hovmöller diagrams shown in Fig. 6a–c and Fig. 6d–f, respectively,  
555 demonstrate that the thicker [ocean model](#) ~~ocean simulated~~ [simulates](#) a stronger MJO  
556 with a frequency closer to [those in the observation and uncoupled experiment C–](#)  
557 [30NS and ERA-I/NOAA data, and more realistic](#) eastward propagation ~~similar to that~~  
558 ~~in C–30NS and observations.~~ In addition, the lead–lag relationship between  
559 precipitation (wind) and SST [was](#) ~~is~~ more realistically simulated with increasing  
560 thickness [of the ocean model](#) (Fig. 6g–i).

561 This result suggests that the thickness of the ~~upper ocean~~ [oceanic mixed layer](#) that  
562 interacts with the atmosphere strongly affects the frequency of the simulated MJO. A  
563 thinner (thicker) oceanic mixed layer is more quickly (slowly) recharged and  
564 discharged through [heat SHF and LHF](#) exchange between the atmosphere and ocean  
565 and therefore likely fluctuates at a faster (slower) tempo. The simulated periodicity is  
566 therefore affected by the thickness of oceanic mixed layer (or [ocean](#) heat content).  
567 Although ~~this study~~ [the result](#) suggests 60 m is an appropriate thickness to realistically  
568 simulate the periodicity of the MJO, we did not intend to suggest the exact thickness  
569 required for a proper simulation because it might depend on the model. The oceanic  
570 mixed layer should be adequately thick to contain a certain amount of heat to generate  
571 [appropriate](#) periodicity ~~that is close to that observed~~. However, the reason for the  
572 intraseasonal time scale (i.e., 20–100 days) should be determined in future studies.  
573 This finding does not suggest a constant periodicity because periodicity might be  
574 affected by the time-varying structure of the atmosphere and ocean in the real world.

575

576 **4.3.4 Effects of coupling domains**

577 The MJO is a planetary-scale phenomenon. Given its large-scale circulation, the  
578 air-sea interaction affecting the MJO likely occurs in a much larger area than the  
579 region near the major convection anomalies. In this section, we discuss ~~whether and~~  
580 ~~how~~ the effect of coupling domain affects aon model's ability to simulate the eastward  
581 propagation speed and periodicity of the MJO. Four experiments considering the  
582 coupling in various domains (C-0\_30N, C-0\_30S, C-30\_180E, and C-30E\_75W,  
583 Fig. 1) were conducted ~~to investigate for~~ the ~~effect of the coupling domain on the~~  
584 ~~eastward propagation speed and periodicity of the MJO in the simulation purpose.~~  
585 The results are shown in Fig. 7. ~~The domains of the four experiments are shown in~~  
586 Fig. 1. The C-0\_30N that considered the coupling in the tropics between the equator  
587 and 30°N ~~simulated~~simulates the least realistic MJO propagation in terms of W-FS  
588 (Fig. 7a), zonal wind-precipitation coupling (Fig. 7e), and SST-precipitation (Fig.  
589 7i) ~~of among~~ the four regional coupling experiments. By contrast, coupling only the  
590 tropics between the equator and 30°S ~~simulated~~simulates a more realistic MJO in all  
591 three aspects (i.e., spectrum in Fig. 7b, temporal evolution of precipitation/wind, and  
592 precipitation/SST coupling in Fig. 7f and 7j). Figure. 8a indicates that the ~~positive~~  
593 ~~precipitation~~negative OLR anomalies at phase 5 simulated in C-0\_30N ~~stayed~~stays  
594 mainly north of the equator and ~~did~~does not shift southward in the MC as  
595 ~~observed~~revealed in ERA-I reanalysis and ~~in~~NOAA OLR and in the control  
596 experiment C-30NS, and the convection over the IO ~~was~~is unrealistically weak. By  
597 contrast, the southward detouring in the MC ~~was~~is realistically simulated in C-0\_30S  
598 that coupled only the tropical ocean between the equator and 30°S. This result  
599 indicates that air-sea coupling occurring south of the equator is the key to producing  
600 appropriate eastward propagation and detouring of the MJO through the MC. Without  
601 this coupling, the C-0\_30N experiment ~~failed~~fails to realistically simulate the  
602 eastward propagation of the MJO. (Fig. 7e). This contrast can be attributed to the-

603 ~~observed~~ warmer ocean surface and higher moisture content found south of the  
604 equator in boreal winter, which comprise a more favorable environmental condition  
605 for air–sea coupling and convection–circulation coupling and the occurrence of the  
606 MJO.

607 MJO simulations can be affected by air–sea coupling in the longitudinal domain.  
608 Tseng et al. (2014) examined this effect by allowing coupling in different regions  
609 (e.g., the IO, WP, and IO + WP) and found that the IO + WP coupling experiment  
610 yielded the most satisfactory MJO simulation in terms of the zonal W–FS and  
611 eastward propagation characteristics. In this study, we conducted sensitivity  
612 experiments in which we allowed coupling in the tropics in two longitudinal domains,  
613 namely 30°E–180°E (C–30\_180E) and 30°E–75°W (C–30E\_75W). The 30°E–180°E  
614 region covered the IO and WP, and the 30°E–75°W region covered the IO and the  
615 entire tropical Pacific. As shown in Fig. 7, the C–30E\_75W experiment ~~simulated the~~  
616 ~~MJO, yielding resultssimulates~~ more ~~similar to the observation and those in C–~~  
617 ~~30NSrealistic MJO~~ than ~~tothe~~ C–30\_180E ~~experiment~~, with stronger eastward  
618 propagation and larger amplitudes in the spectrum (Fig. 7c and 7d) and Hovmöller  
619 diagrams of precipitation/wind (Fig. 7g and 7h) and precipitation/SST (Fig. 7k and  
620 7l). The simulated MJO in C–30E\_75W propagated ~~furtherfarther~~ east than that in C–  
621 30\_180E, particularly ~~evident~~ in Fig. 7k and 7l. The spatial distributions of circulation  
622 and ~~precipitationOLR~~ shown in Fig. 8c and 8d ~~indicatedindicate~~ the presence of a  
623 stronger convective-coupled circulation system over the MC and WP in C–30E\_75W.  
624 These results suggest that coupling over the entire tropical IO and Pacific could  
625 enhance the strength and eastward propagation of the MJO and encourage  
626 ~~furtherfarther~~ propagation to the central Pacific.

627

628 **43.5 Diurnal versus no diurnal cycle in air–sea coupling**

629 ~~The~~Previous studies showed that the diurnal cycle in the MC can weaken the  
630 MJO and its eastward propagation (Hagos et al., 2016; Oh et al., 2013). We conducted  
631 an experiment to determine whether ~~the~~computing surface heat fluxes using daily  
632 mean ~~value~~values, instead of instantaneous values, of atmospheric variables and SST  
633 with the same coupling frequency would affect the MJO simulation. The coupling in  
634 the model was ~~performed~~conducted through ~~heat flux~~the SHF and LHF exchange  
635 between the atmosphere and ocean, ~~that were calculated based on simulated winds,~~  
636 ~~moisture, and temperature.~~ As mentioned in Section 2.3, air-sea fluxes were  
637 calculated twice for every time step (coupling 48 times per day, ~~in the control~~  
638 ~~coupled experiment~~ (C-30NS) based on the instantaneous values of atmospheric and  
639 oceanic variables. In the experiment in which the diurnal cycle was removed (C-  
640 30NS-nD), air-sea fluxes were calculated as in C-30NS but were based on daily  
641 ~~mean data~~means of both atmospheric variables and SST. Doing this removed certain  
642 ~~diurnal effects of air-sea coupling.~~ The results shown in Fig. 9 reveal the enhancement  
643 of the eastward-propagating signals in the MJO (e.g., a larger amplitude in spectrum;  
644 Fig. 9a) and further eastward ~~and faster~~propagation (Fig. 9b) as well stronger  
645 coupling between precipitation and SST (Fig. 9c) ~~in C-30NS-nD.~~ The overall  
646 results are consistent with previous finding that the diurnal cycle tends to reduce the  
647 amplitude ~~and propagation~~of the MJO, indicating that the weakening effect occurs  
648 through air-sea coupling in addition to those processes in the atmosphere. Previous  
649 studies have hypothesized that rapid interaction processes in the diurnal time scale  
650 tend to extract energy from the MJO, thus reducing ~~both~~the strength and propagation  
651 tendency of the MJO. However, a comparison between the spectra of C-30NS and C-  
652 30NS-nD ~~indicated~~indicates that the experiment in which the diurnal cycle ~~was~~is  
653 removed appeared to oversimulate the MJO with unrealistic strength, suggesting that  
654 the effect of the diurnal cycle should be considered in the model to simulate a more

655 realistic MJO. However, whether this is a common result in different models remain  
656 to be examined.

657

658

## 659 **5 4. Discussion and conclusions**

660 Air-sea coupling is a key mechanism for the successful simulation of the MJO  
661 (Chang et al., 2019; DeMott et al., 2015; Jiang et al., 2015, 2020; Kim et al., 2010; Li  
662 et al., 2016; Li et al., 2020; Newman et al., 2009; Tseng et al., 2014). This study,  
663 following the study ~~conducted by~~ Tseng et al. (2014), demonstrated that coupling a  
664 high-resolution 1-D TKE ocean model (namely the SIT model) to the CAM5, namely  
665 the CAM5-SIT, significantly improved the MJO simulation over the standalone  
666 CAM5. The CAM5-SIT realistically simulated By coupling SIT model to an AGCM  
667 different from Tseng et al. (2014), this study confirms the scientific reproducibility for  
668 the improvement of MJO simulation in modeling science. The CAM5-SIT  
669 realistically simulates the MJO characteristics in many aspects (e.g., intraseasonal  
670 periodicity, eastward propagation, coherence in the low-frequency band, detouring  
671 propagation across the MC, tilting vertical structure, and intraseasonal variance in the  
672 WP).

673 Systematic sensitivity experiments were conducted to investigate the effects of  
674 the vertical resolution and the thickness of the 1-D ocean model, coupling domains,  
675 and the absence of the diurnal cycle. The results of all the sensitivity experiments are  
676 summarized in Fig. 10a and 10b, which show four common metrics for MJO  
677 evaluation. The four metrics are the propagation speed of the MJO (estimated from  
678 the U850 Hovmöller diagram as Fig. 2d-f) versus the power ratio of eastward- and  
679 westward-propagating 30–80-day signals (E/W ratio, derived from the zonal W-FS)  
680 in Fig. 10a– and the eastward propagation speed of the 30–80-day filtered

681 precipitation anomaly (estimated from the precipitation Hovmöller diagram) versus  
682 the variance explained by RMM1 and RMM2 (i.e., the sum of the variance explained  
683 by EOF1 and EOF2 based on Wheeler and Hendon, 2004) in Fig. 10b. Based on the  
684 maximum precipitation anomaly and zero values of U850 (indicating deep convection  
685 region), propagation speeds of precipitation and U850 were calculated from  
686 Hovmöller diagrams between 60°E and 150°W. Overall, the control experiment C–  
687 30NS simulates the most realistic MJO among all sensitivity experiments.

688 As for vertical resolution, we determined that the MJO simulation efficiency  
689 decreased when the vertical resolution of the SIT model wasis decreased from 1 m to  
690 12 or 34 m, as observedsimulated in the C–LR12m and C–LR34m experiments,  
691 respectively. This finding, consistent with that reported by Tseng et al. (2014),  
692 suggests that a finer vertical resolution more effectively resolves temperature  
693 variations in the ocean warm layer and enhances atmospheric–ocean coupling, thus  
694 enabling the upper ocean to more efficiently respond to atmospheric forcing by  
695 providing sensible and latent heat fluxes; this results in superior synchronization  
696 between the lower atmosphere and the upper ocean.

697 We observed that the thinnershallower ocean mixed-layermodel bottom could  
698 speed up the eastward propagation of the MJO by producing more perturbations of  
699 shorter periodicity (Fig. 6) and resultedresults in a weaker MJO. The shallower  
700 oceanic mixed layer likely respondedresponds more quickly to atmospheric forcing  
701 but providedprovides less sensible and latent heat fluxes to the atmosphere. Thus, the  
702 MJO propagatedpropagates too fast with a weaker amplitude.

703 In the coupling domain sensitivity experiments, we investigated the essential  
704 coupling domain required to simulate the realistic MJO and the effect of the domain  
705 on the MJO simulation. Coupling only the northern tropics failedfails to simulate the  
706 eastward propagation, whereas coupling only the southern tropics yieldedyields a

707 more realistic MJO simulation, although this simulation [was](#) inferior to coupling the  
708 entire tropics. This contrast reveals the importance of the southern tropical ocean,  
709 especially in the MC where high SST and moisture content are noted. Coupling in the  
710 southern tropics is therefore essential for providing the energy required to maintain  
711 the MJO and its eastward propagation. By contrast, the northern tropics are relatively  
712 dry and cool. Coupling in this region is therefore less effective in improving MJO  
713 simulation.

714 In the longitudinal domain sensitivity experiments, we found that the MJO  
715 amplitude and the eastward extend of its eastward propagation [were](#) enhanced by  
716 extending the eastern boundary of the coupling domain from the tropical eastern IO to  
717 the tropical WP and further to the tropical eastern Pacific (Fig. 1). Further extension  
718 of the domain to cover the tropical Atlantic [did](#) not exhibit further enhancement  
719 (not shown). This result indicates that coupling in the tropical central and eastern  
720 Pacific, although not the major MJO signal regions (i.e., from the tropical IO to the  
721 tropical WP), still played a marked role in sustaining the MJO. We propose the  
722 following to explain this effect. Because of the planetary scale of the MJO, the near-  
723 surface easterly circulation to the east of the convection core often extended to the  
724 tropical central and eastern Pacific where the climatological easterly prevailed. The  
725 coupling beyond the WP increased low-level moisture transport and convergence to  
726 the east of the convection and establish an environment suitable for the further  
727 eastward propagation of the MJO. This effect was likely terminated by the landmass  
728 of Central America when the tropical Atlantic was further included. Thus, a further  
729 eastward extension of the coupling domain exerted little effect on further enhancing  
730 the MJO. A diagnostic study on the effect of the longitudinal coupling domain is  
731 being conducted, and the results will be reported in a following paper.

732 The diurnal versus nondiurnal cycle experiment [indicated](#) that

733 nondiurnal coupling tended to enhance eastward-propagating signals but slow [down](#)  
734 the [eastward](#) propagation. (Fig. 10a–b). This result is consistent with the finding of  
735 previous studies that the diurnal cycle in the atmosphere extracts energy from the  
736 MJO, thus weakening it.

737 In this study, we demonstrated how air–sea coupling can improve the MJO  
738 simulation in a GCM. The findings are as follows.

- 739 (1) Better resolving the fine structure of the upper-ocean temperature and therefore  
740 the air–sea interaction [led](#) to more realistic intraseasonal variability in both  
741 SST and atmospheric circulation.
- 742 (2) An adequate thickness of the oceanic mixed layer is required to simulate a delayed  
743 response of the upper ocean to atmospheric forcing and lower-frequency  
744 fluctuation.
- 745 (3) Coupling the tropical eastern Pacific, in addition to the tropical IO and the tropical  
746 WP, can enhance the MJO and facilitate the further eastward propagation of the  
747 MJO to the dateline.
- 748 (4) Coupling the southern tropical ocean, instead of the norther tropical ocean, is  
749 essential for simulating a realistic MJO.
- 750 (5) Stronger MJO variability can be obtained without considering the diurnal cycle in  
751 coupling.

752 Our study confirmed the effectiveness of air–sea coupling for improving MJO  
753 simulation in a climate model and demonstrated how and where to couple. The  
754 findings enhance our understanding of the physical processes that shape the  
755 characteristics of the MJO.

756  
757 *Code and data availability.* The model code of CAM5–SIT is available at  
758 <https://doi.org/10.5281/zenodo.5510795>. Input data of CAM5–SIT using the

759 climatological Hadley Centre Sea Ice and Sea Surface Temperature dataset and  
760 GODAS data forcing, including 30-year numerical experiments, are available at  
761 <https://doi.org/10.5281/zenodo.5510795>.

762

763 *Author contributions.* HHH is the initiator and the primary investigator of the  
764 Taiwan Earth System Model project. YYL is the CAM5-SIT model developer and  
765 writes the majority part of the paper. WLT and LCJ assist in MJO analysis.

766

767 *Competing interests.* The authors declare that they have no conflict of interest.

768

1095 Table 1. List of experiments

Section	Category	Experiments	Description
43.1	Coupled or uncoupled	A-CTL	Standalone CAM5.3 forced by <del>observed</del> <a href="#">forced by the monthly mean Hadley Centre SST dataset version 1</a> climatology
		C-30NS <del>(the control coupled experiment)</del>	CAM5.3 coupled with SIT over the tropical domain (30° <del>SN</del> -30° <del>NS</del> ), with <a href="#">41 layers of finest vertical resolution</a> (up to <del>submarine-topography</del> <a href="#">the seabed</a> ) and diurnal cycle; the frequency of CAM5 being exchanged with CPL is 48 times per day
43.2	Upper-ocean vertical resolution	C-LR12m	The first ocean vertical level starts at <a href="#">11.85 m with 31 layers</a> (beside SST and cool skin layer <a href="#">are 11.5 m, 29.5 m and 43.6 m up to the seabed</a> )
		C-LR34m	The first ocean vertical level starts at <del>34.2 m</del> <a href="#">33.9 m with 28 layers</a> (beside SST and cool skin layer <a href="#">are 33.9 m, 76.9 m and 96.8 m up to the seabed</a> )
43.3	Lowest boundary of SIT	C-HR1mB10m	The lowest boundary of SIT has a depth of 10 m ( <del>middle-grid</del> <a href="#">model depth between 0 m and 10 m</a> )
		C-HR1mB30m	The lowest boundary of SIT has a depth of 30 m ( <del>middle-grid</del> <a href="#">model depth between 0 m and 30 m</a> )
		C-HR1mB60m	The lowest boundary of SIT has a depth of 60 m ( <del>middle-grid</del> <a href="#">model depth between 0 m and 60 m</a> )
43.4	Regional coupling domain in latitude	C-0_30N	Coupled in the tropical northern hemisphere (0°N-30°N, 0°E-360°E)
		C-0_30S	Coupled in the tropical southern hemisphere (0°S-30°S, 0°E-360°E)
	Regional coupling domain in longitude	C-30_180E	Coupled in the Indo-Pacific (30° <del>SN</del> -30° <del>NS</del> , 30°E-180°E)
		C-30E_75W	Coupled over the Indian Ocean and Pacific Ocean (30° <del>SN</del> -30° <del>NS</del> , 30°E-75°W)
43.5	Absence of the diurnal cycle	C-30NS-nD	Absence of the diurnal cycle in C-30NS; the CAM5.3 daily atmospheric mean of surface wind, temperature, total precipitation, net surface heat flux, u-stress and v-stress over water trigger the SIT and daily mean SST feedback to atmosphere; the frequency of CAM5 is exchanged with CPL 48 times per day

1096 ~~The CAM5.3 AGCM is used in all experiments~~

1097 Experiment abbreviations: “A” means standalone AGCM simulation. “C” means the  
1098 CAM5.3 coupled to the SIT model.

1099 **Figure List**

1100 **Figure 1.** Schematics of coupled and uncoupled domains in the regional coupling  
1101 experiment: (a) C–30NS, (b) C–0\_30N, (c) C–0\_30S, (d) C–30\_180E, and (e) C–  
1102 30E\_75W. The background is the climatological mean SST in December–February (DJF).

1103

1104 **Figure 2.** (a)–(c) Zonal wavenumber–frequency spectra for 850-hPa zonal wind averaged  
1105 over 10°S–10°N in boreal winter after removing the climatological mean seasonal cycle.  
1106 Vertical dashed lines represent periods at 80 and 30 days, respectively. (d)–(f) Hovmöller  
1107 diagrams of the correlation between the precipitation averaged over 10°S–5°N, 75–100°E  
1108 and the intraseasonally filtered precipitation (color) and 850-hPa zonal wind (contour)  
1109 averaged over 10°N–10°S. (g)–(i) Zonal wavenumber–frequency power spectra of  
1110 anomalous OLR (colors) and phase lag with U850 (vectors) for the symmetric component  
1111 of tropical waves, with the vertically upward vector representing a phase lag of 0° with  
1112 phase lag increasing clockwise. Three dispersion straight lines with increasing slopes  
1113 represent the equatorial Kelvin waves (derived from the shallow water equations)  
1114 corresponding to three equivalent depths, 12, 25, and 50 m, respectively. (j)–(l)  
1115 Composites of 20–100-day filtered OLR ( $\text{W m}^{-2}$ , shaded) and 850-hPa wind ( $\text{m s}^{-1}$ ,  
1116 vector) for MJO phase 5 when deep convection is the strongest over the MC and 850-hPa  
1117 wind, with the reference vector ( $1 \text{ m s}^{-1}$ ) shown at the top right of each panel, and (m)–  
1118 (o) 15°N–15°S averaged p-vertical velocity anomaly ( $\text{Pa s}^{-1}$ , shaded) and moist static  
1119 energy anomaly ( $\text{W m}^{-2}$ , contour, interval 0.003); solid, dashed, and thick-black lines  
1120 represent positive, negative, and zero values, respectively. The number of days used to  
1121 generate the composite is shown at the bottom right corner of each panel. (a), (d), (g), (j),  
1122 and (m) are from [observations; the ERA-Interim and NOAA post-processed data \(abbr. ERA-I/NOAA\)](#);  
1123 (b), (e), (h), (k), and (n) are from the [control experiment](#) C–30NS; and  
1124 (c), (f), (i), (l), and (o) are from the A–CTL.

1125

1126 **Figure 3.** Evolution of the filtered OLR anomaly ( $\text{W m}^{-2}$ , shaded) and 850-hPa wind ( $\text{m}$   
1127  $\text{s}^{-1}$ , vector) at phase 2, 4, 6, and 8: (a) [the ERA-I/NOAA data](#), (b) [the control](#)  
1128 [coupled experiment](#) C–30NS, and (c) [the uncoupled experiment](#) A–CTL. The unit of the  
1129 reference vector shown at the top right corner of each panel is  $\text{m s}^{-1}$ , and the number of  
1130 days used for the composite is shown at the bottom right corner of each panel.

1131

1132 **Figure 4.** (a)–(c) Phase-longitude Hovmöller diagrams of 20–100-day filtered  
1133 precipitation ( $\text{mm day}^{-1}$ , shaded) and SST anomaly (K, contour) averaged over 10°N–  
1134 10°S from phase 1 to 8. Contour interval is 0.03; solid, dashed, and thick-black lines  
1135 represent positive, negative, and zero values, respectively. (d)–(f) Phase-vertical  
1136 Hovmöller diagrams of 20–100-day moisture divergence (shading,  $10^{-6} \text{ g kg}^{-1} \text{ s}^{-1}$ ) and

1137 zonal wind (contoured,  $\text{m s}^{-1}$ ) averaged over  $10^{\circ}\text{N}$ – $10^{\circ}\text{S}$ ,  $120$ – $150^{\circ}\text{E}$ ; solid, dashed, and  
 1138 thick-black curves are positive, negative, and zero values, respectively. (g)–(i) Variation  
 1139 of 30–60-day filtered precipitation in the eastern IO and the WP in observation (color  
 1140 shading), and the ratio between intraseasonal and total variance (contoured) and (j)–(l)  
 1141 composites 20–100-day filtered SST (K, shaded) and 850-hPa winds ( $\text{m s}^{-1}$ , vector) at  
 1142 phase 7 when deep convection was the strongest over the dateline. Reference vector  
 1143 shown at the top right corner of each panel. (a), (d), (g), and (j) are from the  
 1144 [observation ERA-I/NOAA data](#); (b), (e), (h), and (k) are from the [control coupled](#)  
 1145 [experiment](#) C–30NS; and (c), (f), (i), and (l) are from the [uncoupled experiment](#) A–CTL.
