Abstract

Accurate description of the wind energy input into ocean waves is crucial to ocean wave modeling and a physics-based consideration on the effect of wave breaking is absolutely necessary to obtain such an accurate description. This study evaluates the performance of an improved formula recently proposed by Xu and Yu (2020), who took into account not only the effect of breaking but also the effect of air-flow separation on the leeside of steep wave crests in a reasonably consistent way. Numerical results are obtained through coupling an enhanced atmospheric wave boundary layer model with the ocean wave model WaveWatch III (v5.16). The coupled model has been extended to be valid in both deep and shallow waters. Duration-limited waves under controlled normal conditions and storm waves under practical hurricane conditions are studied in details to verify the improved model. Both the representative wave parameters and the parameters characterizing the wave spectrum are discussed. It is shown that the improved source-term package for the wind energy input and the wave energy dissipation leads to more accurate results under all conditions. It performs evidently better than other standard source-term options of ST2, ST4 and ST6 embedded in WaveWatch III. It is also demonstrated that the improvement is particularly important for waves at their early development stage and waves in shallow waters.

Keywords: Source-term option; Breaking effect; Atmospheric wave boundary layer model; WaveWatch III; Duration-limited waves; Hurricane-generated waves.

30 **1. Introduction**

31 Accurate modeling of ocean waves depends straightforwardly on a correct formulation
32 of the wind energy supply to the waves through the ocean surface as well as the wave
33 energy dissipation within the ocean surface layer, and eventually on a thorough
34 understanding to the physics underlying these two dynamic processes. The wind energy
35 input supports the generation and growth of ocean waves, while the wave energy dissipation
36 always occurs owing not only to the viscous property of the fluid but also to the effects of
37 turbulent mixing and multiphase interaction that take place in the boundary layer at both
38 sides of the air-sea interface. In the past decades, a tremendous number of research efforts
39 have been made to enhance our understanding on the phenomena of wind energy input into
40 ocean waves and the dissipation of ocean surface waves due to various mechanisms
41 (Janssen, 1989; 1991; 2004; Hasselmann et al., 1973; Snyder et al., 1981; Donelan et al.,
42 2006; Babanin et al., 2007; Ardhuin et al., 2010; Rogers et al., 2012). However, a
43 comprehensive integration of the accumulated knowledge, particularly those developed
44 under extreme conditions in shallow waters, does not seem to have been satisfactorily
45 achieved up to date.

46 Janssen (1989; 1991; 2004) proposed the most classical formula for the wind energy
47 input based on the resonance theory of Miles (1957; 1965), in which the wind drag as a
48 deterministic function of the roughness height of the ocean surface is a critical parameter.
49 Hasselmann et al. (1973) obtained an expression for the wind energy input by solving the
50 wave energy equation and then calibrating parameters with field data from the joint North
51 Sea wave project (JONSWAP). Snyder et al. (1981) and Donelan et al. (2006) conducted
52 field experiments in the Bight of Abaca, Bahamas, and Lake George, Australia, and included
53 more physics in their formula for the wind energy input. Badulin et al. (2007) and Zakharov
54 et al. (2012; 2017) proposed a new method to establish a theory for the wind energy input
55 by considering the weakly turbulent law for wind-wave growth. In spite of these important
56 achievements, the wind energy input is still not yet satisfactorily formulated, basically due
57 to complexity of the phenomenon as well as the physics underlying the phenomenon.

58 Researchers have found substantial differences between wind energy input through

59 ocean surfaces with and without wave breaking (Banner and Melville, 1976). Data collected
60 during the AUSWEX field campaign at Lake George, Australia (Babanin et al., 2007)
61 showed that under a severe breaking condition, the wind energy input will increase to about
62 2 times of that under a relevant non-breaking condition. Although the important effects of
63 wave breaking as well as short-wave dissipation on wind energy input have been well
64 understood (Janssen, 1989, 1991; Makin and Kudryavtsev, 1999; Hasselmann et al., 1973;
65 Babanin et al., 2007), it is only until recent that Xu and Yu (2020) proposed a formula to
66 effectively include these effects. Xu and Yu (2020)'s formula takes into consideration both
67 the breaking effect and the effect of air-flow separation on the leeside of steep wave crests
68 in a reasonably consistent way. Despite of its physics-based nature, a further evaluation of
69 its performance in practical and more complicated wind wave conditions, however, is still
70 necessary.

71 It is generally believed that, among the total wind energy transferred into the ocean
72 waves, a part is absorbed by the long-wave components to support wave growth while an
73 even larger part is received by the short-wave components and quickly dissipated due to
74 fluid viscosity, wind shear on the ocean surface and the turbulence effect related to wave
75 breaking (Csanady, 2001; Jones and Toba, 2001). Formulation of the wave dissipation,
76 however, is very difficult and the available suggestions in the literature are rather
77 controversial (Cavaleri et al., 2007). The earliest wave dissipation model is known to be the
78 probabilistic breaking model originally presented by Longuet-Higgins (1969) and then
79 improved by Yuan et al. (1986). Hasselmann (1974) proposed the whitecap model based on
80 a mathematical formulation of the negative work done by the downward whitecap pressure
81 on the upward wave motion. Phillips (1985) and Donelan and Pierson (1987) proposed the
82 quasi-saturation model by assuming a local equilibrium relationship among wind energy
83 input, nonlinear transfer and wave dissipation. Polnikov (1993) preferred the turbulence
84 dissipation model which relates the loss of wave energy to the dissipation of turbulence
85 kinetic energy. In addition to the theoretical studies, a significant number of experimental
86 investigations have also been carried out (Phillips et al., 2001; Melville and Matusov, 2002;
87 Donelan, 2001; Hwang, 2005). Based on the data measured at Lake George, Australia,

88 Bananin and Young (2005) established an empirical model, in which the concept of
89 cumulative effect is introduced so that the contribution of low-frequency wave motion to
90 breaking of high-frequency waves can be taken into account. It may be necessary to point
91 out that most of the experimental studies are supported only by limited data.

92 WaveWatch III (WWIII), a successful third-generation wave model, has been widely
93 used for simulating ocean waves in both deep and shallow waters. With great efforts made
94 by scientists around the world (Ardhuin et al., 2010; Zieger et al., 2015), parameterizations
95 of the source terms in WWIII have been well calibrated under various conditions to achieve
96 satisfactory results for evolution of an ocean wave spectrum. Under severe wave conditions,
97 however, their accuracy is often unsatisfactory and the wave energy is underestimated even
98 with an optimal choice of the parameters (Cavaleri et al., 2020; Campos et al., 2018;
99 Mentaschi et al., 2015). Meanwhile, researchers found that the directional wave spectrum
100 has been sometimes very poorly simulated even when the significant wave parameters are
101 accurately represented (Fan and Rogers, 2016). Stopa et al. (2016) believed that all wave
102 models have difficulty in describing the directional spread of waves. Although modelers
103 usually tend to attribute the numerical error to the inaccuracy of the wind data or topography
104 data, we must admit that imperfection of the source term parameterization, especially under
105 severe wave conditions, is also one of the main reasons.

106 In this study, improved formulas for the wind energy input and the wave energy
107 dissipation are embedded into the WWIII version 5.16, though it may also be applied to
108 other ocean wave models. The enhanced atmospheric wave boundary layer model (AWBLM)
109 (Xu and Yu, 2021) is also coupled to ensure a more accurate wind stress evaluation at high
110 wind speed and in finite water depth. The performances of the improved formulas are
111 evaluated under both idealized wind conditions and real extreme conditions. Attention is
112 also paid to their differences in deep- and shallow-waters. The structure of the paper is
113 arranged as follows. The improved formulation as well as the framework of the coupled
114 AWBLM-WWIII model are described in Section 2. Model verification under controlled
115 conditions is presented in Section 3, while model verification under extreme wind
116 conditions is presented in Section 4. Section 5 is a summary of conclusions.

117 2. Model Description

118 2.1 Coupled AWBLM-WWIII Model

119 The ocean wave model WaveWatch III numerically solves the energy conservation
120 equation for wave action density spectrum (WW3DG, 2016):

$$121 \quad \frac{DN}{Dt} = \frac{S}{\omega} \quad (1)$$

$$122 \quad S = S_{in} + S_{ds} + S_{nl} \quad (2)$$

123 where $N(\omega, \theta)$ is the wave action density spectrum; ω is the relative frequency; S is
124 the source/sink term given by Eq. (2). In general, the source term S must represent three
125 different mechanisms: the wind energy input into waves S_{in} , the wave energy dissipation
126 S_{ds} , the nonlinear wave-wave interaction S_{nl} . Although S_{in} and S_{ds} represent different
127 physical processes, they should be considered and calibrated interrelatedly since the net
128 effect of these two sources rather than each of them can be more accurately measured on
129 many occasions and it is the net effect that governs the growth/decay of the ocean waves.
130 S_{nl} plays a key role in the evolution of wave spectrum shape and may, at least theoretically,
131 be evaluated through correctly solving the nonlinear transfer integrals. Note that, in shallow
132 waters, the wave energy dissipation must include those due to bottom friction and
133 depth-induced breaking, denoted by S_{dsf} and S_{dsb} , respectively, in addition to that due to
134 whitecaps, denoted by S_{dsw} , i.e., $S_{ds} = S_{dsf} + S_{dsb} + S_{dsw}$. It may also be worthwhile
135 mentioning that an accurate evaluation of the nonlinear interaction effect is surprisingly
136 difficult for the high-frequency wave components, particularly in shallow waters. Therefore,
137 it is frequently suggested to apply a semi-empirical theory for evaluating S_{nl} , i.e., let
138 $S_{nl} = S_{nl4} + S_{nl3}$, where S_{nl4} and S_{nl3} are expressed as functions of the wave frequency
139 as well as the wave direction, and represent the quartet and triad wave interactions, which
140 play dominant roles in deep and shallow waters, respectively.

141 In order to accurately simulate ocean waves under moderate to severe wind conditions,
142 and from deep to shallow water conditions, an advanced atmospheric wave boundary layer
143 model (AWBLM) must be coupled into WWIII for a dynamic evaluation of the wind stress.

144 The AWBLM applicable for this purpose is well described in Xu and Yu (2021), which may
145 take effects of both ocean surface state and water depth into consideration, and has certain
146 advantages compared to a simple quadratic formula for the wind stress. In the coupled
147 model, the source terms are treated in the following way. Quartet-wave interaction is
148 computed with the standard discrete interaction approximation (DIA). Note that, though it
149 may bring some uncertainty into the numerical results for nonlinear effects, the DIA method
150 is still widely employed in practical applications due to its minimum requirement on the
151 computational efforts (Liu et al., 2017; Stopa et al., 2015; Ardhuin et al., 2010). Triad-wave
152 interaction is evaluated with the Lumped Triad Approximation model (Eldeberky, 1996).
153 The bottom friction effect is described by the simple model of JONSWAP (Hasselmann et
154 al., 1973). The Battjes and Janssen (1978) parameterization is employed to represent the
155 effect of depth-induced breaking. The parameters included in all source terms except for
156 those with special emphases follow the default setting. The wind energy input and the wave
157 energy dissipation are considered as a package in this study. WWIII provides four typical
158 options of this package, i.e., ST2, ST3, ST4, ST6, among which ST3 and ST4 are based on
159 the same formulation of Janssen (2004) for the wind energy input. Since ST4 has been
160 frequently reported to have a better performance than ST3 (Stopa et al., 2016; Beyá et al.,
161 2017; Liu et al., 2017), the ST3 option is neglected in this study. The standard options are
162 carefully compared with the improved model proposed by the present authors (Xu and Yu,
163 2020).

164 2.2 Improved Model of Xu and Yu (2020)

165 The wind energy input in the improved model of Xu and Yu (2020), hereafter referred as
166 ST-XY option, is expressed by

$$167 \quad S_{\text{in}}(k, \theta) = \frac{\rho_a}{\rho_w} \omega \gamma_g(k, \theta) E(k, \theta) \quad (3)$$

$$168 \quad \gamma_g(k, \theta) = a \left[b_T \lambda G' + 1 - b_T G \right] W^2 \sqrt{B_n} \quad (4)$$

$$169 \quad W = \max \left(0, \frac{U_{10}}{c_p} \cos(\theta - \theta_a) - 1 \right) + a_0 \min \left(0, \frac{U_{10}}{c_p} \cos(\theta - \theta_a) - 1 \right) \quad (5)$$

170
$$B_n k = A k \int_0^{2\pi} k^3 E k, \theta' d\theta' \quad (6)$$

171
$$b_T k = 89.5 \sqrt{B_n k} - 0.0223^2 \quad (7)$$

172
$$G = 2.8 - 1.0 \left[1 + \tanh \left[10 \sqrt{B_n} \left(\frac{U_{10}}{c_p} \cos \theta - \theta_a - 1 \right)^2 - 11 \right] \right] \quad (8)$$

173 where ρ_a is the density of air; ρ_w is the density of water; ω is radian frequency; k is
 174 the wavenumber, which is related to ω through the dispersion relation; θ is the wave
 175 direction; $E k, \theta$ is the directional wave energy spectrum; $\gamma_g k, \theta$ is the wave growth
 176 rate; c_p is the celerity of the wave with peak frequency; U_{10} is the wind speed at the 10 m
 177 level above the ocean surface; θ_a is the wind direction. Note that the basic form of Eq. (3)
 178 follows the conventional assumption that S_{in} is proportional to the directional wave
 179 spectrum. However, the most crucial factor in S_{in} , i.e., the wave growth rate γ_g is
 180 formulated to represent the effect of various physical processes. Although γ_g is essentially
 181 governed by the relative wind speed and the mean steepness of the surface waves, it is
 182 considered to be essentially different when wave breaking does or does not occur, and is
 183 thus expressed as a weighted average of the different multipliers corresponding to breaking
 184 and non-breaking conditions with the breaking probability b_T being the weight. The
 185 relative wind speed is expressed by Eq. (5), where deflection of the wind direction from the
 186 wave direction is fully considered. It may be necessary to point out that the contribution of
 187 the inverse wind to energy input is reduced by a factor of $a_0 = 0.45$ following Liu et al.
 188 (2017). Under the non-breaking condition, a separation coefficient G is introduced to
 189 represent the ‘shelter effect’ due to airflow separation at the lee side of high wave crests
 190 following Donelan et al. (2006). When wave breaks, the ‘shelter effect’ disappears and G
 191 reduces to its maximum value $G' = 2.8$. Since wave breaking has an effect of intensifying
 192 wind energy input, we introduce an amplification factor λ , and let $\lambda = 2.0$, also
 193 following previous studies. It may also be necessary to mention that the wave steepness is
 194 related to the saturated wave spectrum $B_n k$, as expressed by Eq. (6), where $A k$ is a

195 measure of the directional spectrum width. In general, the wind energy input is positive, but
 196 it may become negative when a strong swell is in presence and the wind speed is smaller
 197 than the wave celerity or when the direction of wind is significantly deflected from the wave
 198 direction.

199 The advantage of the wind energy input in the improved model of Xu and Yu (2020) is
 200 its direct representation of the underlying physics. Based on the field observations of both
 201 Donelan et al. (2006) and Babanin et al. (2007), the wind energy input into waves under
 202 severe conditions is a very complicated process, since random waves may break and may
 203 not break depending on the instantaneous local wave steepness. For non-breaking waves,
 204 air-flow separation occurs on the leeside of wave crests, and the wind energy input reduces.
 205 For breaking waves, the wind energy input is significantly larger due to breaking induced
 206 mixing. The improved model of Xu and Yu (2020) fully considers these two effects and,
 207 consequently, should be more suitable for the description of severe waves.

208 Since the ocean wave development depends actually on the net energy gain in the ocean
 209 surface layer and it is sometimes very difficult to identify if some amount of wind energy is
 210 transferred into the ocean waves and then dissipated or it is dissipated within the
 211 atmospheric boundary layer and not received by the ocean at all, S_{in} and S_{ds} must then
 212 be considered as a package. In other words, formulation of the dissipation term should be
 213 based on a relevant definition of the wind energy input. In this study, we follow the wave
 214 dissipation model of Ardhuin et al. (2010) for the whitecap effect. The semi-empirical
 215 dissipation model of Ardhuin et al. (2010) can be expressed as (see also Leckler et al., 2013)

$$216 \quad S_{dsw} = S_{dsn} + S_{dsc} \quad (9)$$

$$217 \quad S_{dsn} = \xi_n B_r^{-2} \omega \delta_d \max[B k - B_r, 0]^2 + 1 - \delta_d \max[B' k, \theta - B_r, 0]^2 E k, \theta \quad (10)$$

$$218 \quad S_{dsc} = -1.44 \xi_c \left\{ \int_0^{r_c k} \int_0^{2\pi} \max[\sqrt{B k', \theta'} - \sqrt{B_r}, 0]^2 \Delta c_p d\theta' dk' \right\} E k, \theta \quad (11)$$

219 where, ξ_n and ξ_c are empirical constants; δ_d is a factor introduced to weight the
 220 isotropic part and direction-dependent part; r_c is the minimum ratio of the wavenumber

221 that will wipe out the short waves. The saturation spectrum $B_n(k)$ is defined in the same
 222 way as before and the directional saturation spectrum $B_n'(k, \theta)$ is defined by

$$223 \quad B_n'(k, \theta) = \int_{\theta - \Delta_\theta}^{\theta + \Delta_\theta} k^3 \cos^2(\theta - \theta') E(k, \theta') d\theta' \quad (12)$$

224 The threshold of $B_n(k)$ is denoted by B_r . Note that Eqs. (9), (10) and (11) are based the
 225 assumption that wave dissipation consists of an inherent effect and a cumulative effect, both
 226 are proportional to the directional wave spectrum. In shallow waters, dissipations due to
 227 bottom friction and depth-induced breaking are formulated following Xu and Yu (2021).

228 2.3 Standard Models

229 Known reliable formulas for the wind energy input and the wave energy dissipation
 230 have been embedded in WWIII. Among all, the following options, which have been widely
 231 preferred on different occasions, are chosen for comparison in this study.

232 **(1) ST2 option.** This package, originally proposed by Tolman and Chalikov (1996),
 233 consists of the wind energy input formula of Chalikov and Belevich (1993) and Chalikov
 234 (1995) as well as a relevant wave energy dissipation model. The dissipation model
 235 emphasizes the different mechanisms of dissipation for low- and high-frequency waves. The
 236 expression for low-frequency waves is based on an analogy to energy dissipation due to
 237 turbulence, while that for high-frequency waves is purely empirical. A linear combination of
 238 these two expressions then represents the total dissipation. It has been reported that this
 239 wind energy input formula may need to be filtered using a special technique when a strong
 240 swell is in presence (Tolman, 2002). For the purpose of comparison, the default setting of
 241 parameters in this study follows Tolman (2002), who selected this package in WWIII for a
 242 global ocean wave modeling and obtained satisfactory results.

243 **(2) ST4 option.** This package consists of the wind energy input formula of Janssen
 244 (2004), which is based on the wave growth theory of Miles (1957), and the wave energy
 245 dissipation model of Ardhuin et al. (2010). The dissipation model appears as the summation
 246 of an inherent part and a cumulative part. All parameters are determined following Ardhuin
 247 et al. (2010).

248 **(3) ST6 option.** This package consists of the formulas for wind energy input and wave

249 energy dissipation due to whitecaps which fit the field data obtained at Lake George,
250 Australia (Donelan et al., 2006; Rogers et al., 2012). A sink term due to negative wind
251 energy input is considered for inverse winds. The dissipation due to whitecaps is expressed
252 as the sum of an inherent part, which is proportional to wave spectrum, and a cumulative
253 part in terms of the integral properties of the wave spectrum below a certain value of the
254 wavenumber.

255 **3. Model Verification under Controlled Normal Conditions**

256 **3.1 Duration-limited waves in deep waters**

257 The ideal problem of wave development over the open sea of infinite water depth is
258 considered. At a given duration, evolution of the directional wave spectrum is simulated
259 with WWIII considering different choices of the source-term package. The uniform wind
260 speed at the 10 m height above ocean surface is fixed at a moderate level of 10 m/s.
261 Sensitivity of the numerical results to the computational time step is also studied. It is
262 shown that a spatial resolution of $1/30^\circ$ is reasonably accurate for duration-limited wave
263 simulations and a finer grid does not lead to any significant change of the numerical results.
264 The boundary effect in the numerical results is minimized in this case by setting open
265 boundary conditions surrounding a large-enough computational domain. It is also
266 demonstrated that little difference of the numerical results can be observed as the
267 computational time step takes 30 s, 1 min and 10 min. Therefore, the results obtained with
268 the time step equal to 10 min are presented in the remaining part of this study.

269 In Figure 1, the wave growth curve, i.e., the relationship between the normalized total
270 wave energy ε and the normalized duration τ , computed with different options for the
271 source terms, is presented and compared with the empirical results available in the literature.
272 The four empirical growth curves correspond to Stewart's (1961) law, which was originally
273 presented as tabulated data, Sanders' (1976) law, the CERC (1977) law and Kahma and
274 Calkoen's (1992) law. The equilibrium value given by the Pierson-Moskowitz spectrum
275 (Pierson and Moskowitz, 1964), i.e., $\varepsilon_{PM} = 3.6 \times 10^{-3}$, as well as the tabulated values of
276 Moskowitz (1964) are also plotted.

277

278 Figure 1. Comparisons of duration-limited growth rate between empirical and computational
 279 results. Both wave energy and duration are nondimensionalized with U_{10}

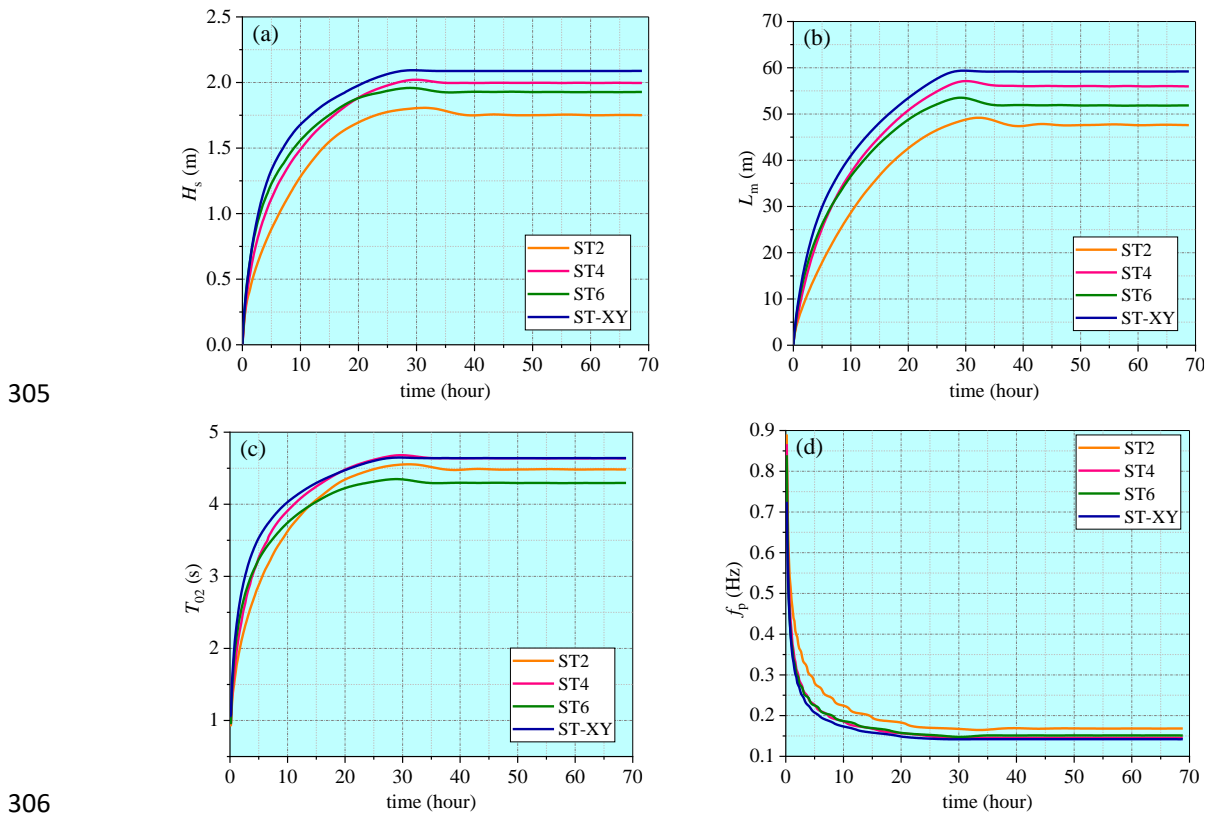

280

281 By comparing the computed wave growth curves with each other and with the empirical
 282 results as well, it becomes clear that, the WWIII model results with different choices of the
 283 source-term package are all rather close to the CERC (1977) law and Kahma and CalKoen's
 284 (1992) law, and also agree with the results of Rogers et al. (2012). At a younger wave age,
 285 particularly at $\tau < 2 \times 10^3$, the ST-XY option performs much better while other
 286 source-term options underestimate the wave energy significantly. The ST4 option most
 287 severely underestimate the wave energy at the early stage of wave development. As duration
 288 increases, the results of the ST6 option approaches those of the ST-XY option. When
 289 approaching the equilibrium stage ($10^4 < \tau < 10^5$), the numerical results corresponding to
 290 ST-XY, ST6 and ST4 options all approach the Pierson-Moskowitz limit while the ST2
 291 option still underestimate the wave energy. In general, the performance of the ST-XY option
 292 is obviously better.

292

293 Since the source terms are often formulated in terms of the mean wave parameters,
 294 evolution of the wave spectrum and development of the mean wave parameters are thus
 295 interdependent. Therefore, a comparison of the mean wave parameters obtained with
 296 different choice of the source term options, as presented in Figure 2, is highly meaningful. It
 297 is demonstrated that the significant wave height H_s and the mean wavelength L_m obtained
 298 with the ST-XY option are slightly greater than the results obtained with other options while
 the ST2 option yields the smallest values. The numerical result of the mean wave period T_{02}

299 obtained with the ST-XY option is the largest at the early wave development stage, but it
 300 becomes almost the same as that obtained with the ST4 option at the equilibrium stage. The
 301 mean wave period T_{02} obtained with the ST2 option is the smallest at the early
 302 wave-development stage while that obtained with the ST6 option becomes smallest at the
 303 equilibrium stage. The peak frequency f_p obtained with ST4, ST6 and ST-XY options is very
 304 close to each other, but the ST2 option results in a larger value.

307 Figure 2. Comparisons of numerical results for (a) significant wave height H_s , (b) mean
 308 wave length L_m , (c) mean wave period T_{02} and (d) peak frequency f_p , obtained with different
 309 choices of the source-term options.

310 A comparison of the computed spectra of the wind energy input and the wave energy
 311 dissipation with different choices of the source-term options is presented in Figure 3. Note
 312 that the spectra obtained with the ST2 option are not presented since they are obviously
 313 underestimated. The numerical results strongly indicate that the wind energy input and the
 314 wave energy dissipation resulted from the same source-term package are correlated, not
 315 only in terms of the peak values but also in terms of the spectral shapes. It is seen that, the

316 wind energy input resulted from the ST-XY option maintains at a higher level than those
 317 resulted from other options at the early wave-development stage, leading to a faster wave
 318 growth and higher level of the wave energy at younger wave ages. Relatively concentrated
 319 unimodal distributions for both the wind energy input and the wave energy dissipation are
 320 built at the early wave-development stage, no matter which source-term option is adopted.
 321 As wave development continues, however, the peak frequencies as well as the peak values
 322 of the spectra decrease while more wind energy is transferred to the higher frequency waves
 323 and bimodal distributions are formed. At this stage, the peak value of the spectra obtained
 324 with the ST-XY option is similar to those obtained with the ST6 and ST4 option, while its
 325 high-frequency part has higher values than those resulted from the ST6 and ST4 options.
 326 When approaching the fully-developed stage, the wind energy input obtained with the
 327 ST-XY and ST4 options reaches a peak at relatively low frequency, but the peak obtained
 328 with the ST6 option appears at a much higher frequency. This is related to whether the
 329 breaking effect is fully considered when formulating the wind energy input.

330

331

332 Figure 3. Spectra of the wind energy input and the wave energy dissipation obtained with
 333 different choices of the source-term package.

334

335

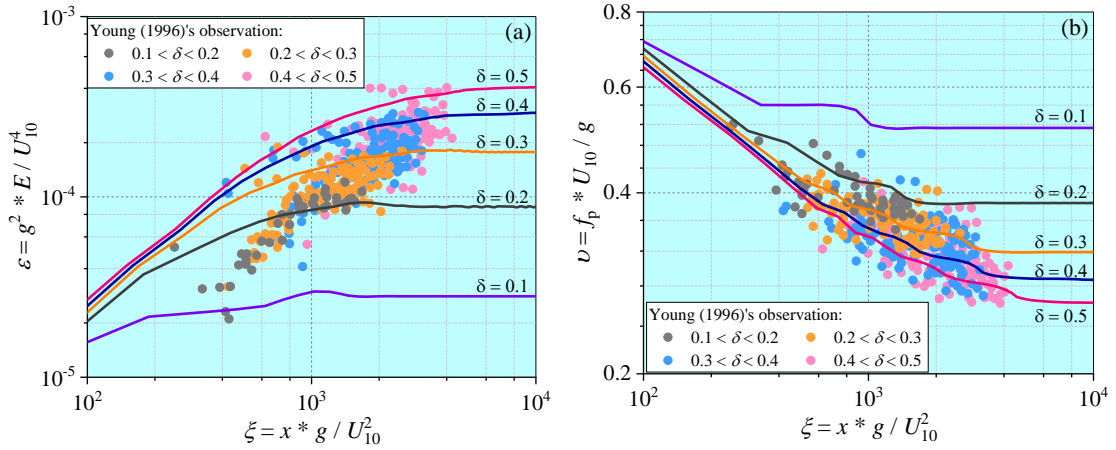

336 Figure 4. Deepwater spectra of wind energy input under breaking and non-breaking
 337 conditions at different wave development stages given by the ST-XY source-term option

338 A major merit of the improved formula for the wind energy input of Xu and Yu (2020)
 339 is the inclusion of breaking effect and the effect of airflow separation on the leesides of
 340 steep waves. Among the total wind energy input, the portions taking place under breaking
 341 and non-breaking conditions, given by the improved formula of Xu and Yu (2020), are
 342 presented in Figure 4. It is clearly demonstrated that, at the early wave-development stage,
 343 over 60% of the peak wind energy input takes place under the breaking condition. As wave
 344 development continues, the proportion of the peak wind energy input under breaking
 345 conditions decreases rapidly. When approaching the equilibrium stage, only 15% of the peak
 346 wind energy input happens under breaking conditions. The trend suggested by our
 347 numerical results is in very good agreement with the facts reported in previous studies
 348 (Janssen, 1989; Hasselmann et al., 1973). Field observations indicate that wind energy input
 349 into breaking waves is about 2 times larger than that into non-breaking waves (Donelan et
 350 al., 2006; Babanin et al., 2007). Because of a relatively large amount of wind energy input
 351 into the breaking wave components in the early wave-development stage, one observes a

352 faster wave growth and higher level of the wave energy at younger wave ages. It is thus
353 reasonable to conclude that the ST-XY option for the wind energy input and the wave
354 energy dissipation successfully integrated the known information about the effect of
355 breaking on the wind energy input and improved the performance of the WWIII model,
356 especially at the early wave-development stage when the wave energy has often been
357 underestimated.

358 **3.2 Duration-limited waves in shallow waters**

359 In order to evaluate its performance in nearshore environment, the ST-XY source-term
360 option is also applied to the simulation of duration-limited waves in shallow waters. The
361 computational conditions are the same as those adopted in the deep-water case except for a
362 varying water depth from 5 m to 1 m. The nondimensional water depth $\delta = gd/U_{10}^2$ then
363 varies from 0.5 to 0.1. The computational results are compared with field observations of
364 Young and Verhagen (1996), who systematically measured the variations of wave
365 parameters and wave spectrum in shallow waters. Since the measured data was provided in
366 a fetch-limited manner, the method of Hwang and Wang (2004) is used to transfer the
367 duration-limited numerical results to fetch-limited ones for comparison. As demonstrated in
368 Figure 5, the numerical results obtained with the ST-XY source-term option in shallow
369 waters match well with the field data. As the nondimensional water depth increases from 0.1
370 to 0.5, the wave energy increases while the peak frequency decreases. This is well explained
371 by the effect of water depth on wave steepness and wave height. Within each range of the
372 water depth, the field data basically fall into the relevant two curves resulted from the model.
373 This is particularly accurate for the wave energy. Therefore, it may be concluded that the
374 improved source-term option of Xu and Yu (2020) is also effective for ocean wave modeling
375 under shallow water conditions.

376

377 Figure 5. Comparisons of (a) fetch-limited growth rate and (b) wave age variation between
 378 measured and computed results.

379

380

381 Figure 6. Spectra of wind energy input under breaking and non-breaking conditions resulted
 382 from the ST-XY source-term package at different wave development stages in a water depth
 383 of 2 m

384

385 Figure 7. Variations of the percentage for wind energy input under breaking and
 386 non-breaking conditions. Solid lines are those under breaking condition while dot-dash lines
 387 are those under non-breaking condition. Different colors stand for different wave ages.

388 Intensified breaking is a major feature of the shallow water waves. Correct
 389 representation of the breaking effect in the wind energy input is thus very important for
 390 modeling shallow water waves. Different from the deep-water situation, the peak value of
 391 the wind energy input taking place under breaking conditions are always higher than under
 392 non-breaking conditions all through the early wave-development stage to the equilibrium
 393 stage, as presented in Figure 6. The wind energy input taking place under breaking
 394 conditions remains a high proportion even at the equilibrium stage, indicating a more
 395 frequent breaking in shallow waters. In figure 7, the percentages of the wind energy input
 396 taking place under breaking and non-breaking conditions at different water depths and
 397 different stage of wave development are shown. At each wave development stage, the
 398 percentage taking place under the breaking condition increases as the water depth decreases.
 399 At a given water depth, the breaking effect is more prominent at younger wave age but is
 400 still important at the equilibrium stage.

401 4. Model Verification under Practical Extreme Conditions

402 Storm waves under hurricane winds are characterized by the general young wave age
 403 and intensive breaking process, due to the extreme wind speed and rapid-changing wind
 404 directions. Therefore, their modeling requires an accurate description of the wind energy
 405 input to represent such characteristics. In this section, the effectiveness of the ST-XY

406 source-term option is evaluated. Hurricane Ivan (2004) and Hurricane Katrina (2005), both
 407 of which made landfalls at the coastline of Gulf of Mexico, are chosen for our verification
 408 purpose. Hurricanes Ivan and Katrina are both typical, long-lived, category 4-5 tropical
 409 cyclones with well recorded observational data. In fact, Hurricanes Ivan and Katrina have
 410 been extensively modeled and studied in the literature (Wang et al., 2005; Moon et al., 2008;
 411 Fan et al., 2009; Zieger et al., 2015). In addition, since the tracks of the two hurricanes lie in
 412 the same ocean basin, data of the topography, the forced wind and the ocean currents can be
 413 obtained from the same source, and the model settings can also be kept the same.

414 4.1 Available data

415 It is very natural to require possibly most accurate wind data for reliable model results
 416 on ocean wave development (Campos et al., 2018). In this study, we blend the H*wind data
 417 (resulted from the Real-time Hurricane Wind Analysis System operated by the Hurricane
 418 Research Division, National Oceanic and Atmospheric Administration) with the ECMWF
 419 (European Centre for Medium-Range Weather Forecasts) data to build the necessary wind
 420 field. The H*wind dataset integrates all field data available during a hurricane event and is
 421 usually considered to be highly accurate in a certain range affected by the relevant hurricane
 422 (Fan et al., 2009; Liu et al., 2017; Chen and Yu, 2017). The H*wind data is issued every 3 h
 423 with a grid resolution of 6 km and a spatial extent of $8^\circ \times 8^\circ$ around the hurricane center.
 424 Because the H*wind data does not cover the entire simulation domain, the ECMWF data
 425 must be supplemented. The ECMWF data has a spatial resolution of 0.125° and temporal
 426 resolution of 6 h, which is good enough to represent the background wind field. The wind
 427 data from different sources is combined by setting a transition zone so that

$$428 \quad \mathbf{U}_{10} = \begin{cases} \mathbf{U}_H & r < R_{\max} \\ \frac{R_{\max} - r}{0.3R_{\max}} \mathbf{U}_H + \frac{r - 0.7R_{\max}}{0.3R_{\max}} \mathbf{U}_E & 0.7R_{\max} < r < R_{\max} \\ \mathbf{U}_E & r > R_{\max} \end{cases} \quad (13)$$

429 where, \mathbf{U}_H and \mathbf{U}_E denote the wind velocity vectors from the H*wind dataset and the
 430 ECMWF dataset, respectively; r is the distance from the hurricane center; R_{\max} is the

431 maximal distance of the H^* wind boundary to the hurricane center. The time interval of the
 432 wind field is interpolated to 0.5 h to satisfy the computational condition. The normalized
 433 interpolation method of Fan et al. (2009), which ensures the greatest likelihood that the
 434 structure of hurricane wind field is not affected by the interpolation, is applied for this
 435 purpose. The wind field constructed in such a manner agrees well with the buoy data as
 436 shown in Figures 8 and 9. To include the effect of ocean currents (Fan et al., 2009), the
 437 global reanalysis database generated with HYCOM (HYbrid Coordinate Ocean Model) and
 438 NCODA (Navy Coupled Ocean Data Assimilation) is also utilized as the model input. The
 439 data has a spatial resolution of $1/12^\circ$ and a temporal resolution of 3 h. The topography data
 440 is from the ETOPO1 datasets and has a spatial resolution of $1'$.

441 Buoy data published by NDBC (National Data Buoy Center, National Oceanic and
 442 Atmospheric Administration) are used to validate the model results on representative wave
 443 parameters including H_s , T_{02} and spectral wave parameters in both deep- and shallow waters.
 444 The locations of buoys are shown in Figure 10.

447 Figure 8. Comparison of reconstructed time series of wind velocity with observed data at
 448 locations of the NDBC buoys during Hurricane Ivan. Scattered dots and triangles are buoy
 449 data of wind speed and wind direction, respectively. Blue and red lines are constructed wind
 450 speed and wind direction, respectively.

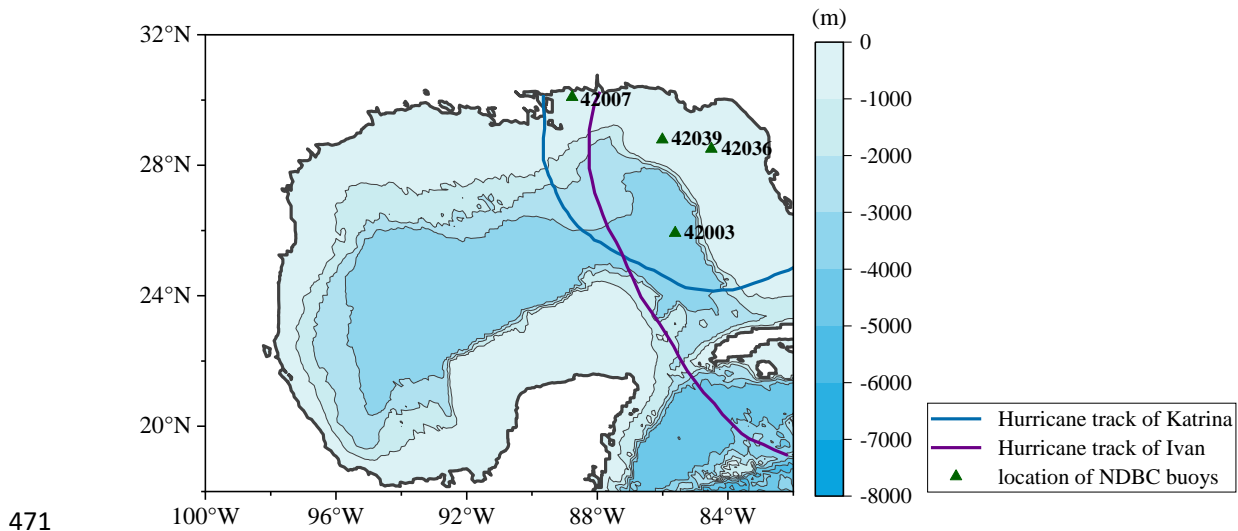

451

452

453 Figure 9. Comparison of reconstructed time series of wind velocity with observed data at
 454 locations of the NDBC buoys during Hurricane Katrina. Scattered dots and triangles are
 455 buoy data of wind speed and wind direction, respectively. Blue and red lines are constructed
 456 wind speed and wind direction, respectively. At buoy 42003 and 42007, there is data
 457 missing.

458 **4.2 Model setup**

459 The computational domain, as shown in Figure 10, covers the area affected by both
 460 Hurricane Ivan (2004) and Hurricane Katrina (2005), ranging from 100°W to 82°W and
 461 from 18°N to 32°N within Gulf of Mexico. Considering a minimal time period for model
 462 warm-up, simulation of Hurricane Ivan is initialized at 00:00 UTC, 12 September 2004 and
 463 continues for nearly 4 days until 21:00 UTC, 15 September 2004. Simulation of Hurricane
 464 Katrina is initialized at 00:00 UTC, 25 August 2005 and continues for nearly 7 days until
 465 18:00 UTC, 31 August 2005. A time step of 10 min is fixed. The simulation is performed
 466 over the geographical coordinate system with a resolution of 1/12°. We assume 36
 467 directional intervals with a constant increment of 10° and 35 frequency intervals that
 468 increase logarithmically over the range of 0.0373-1.048 Hz. The numerical results obtained
 469 with the ST-XY source-term option are compared to those obtained with other options. The
 470 ST2, ST4, ST6 options are implemented with the default setting.

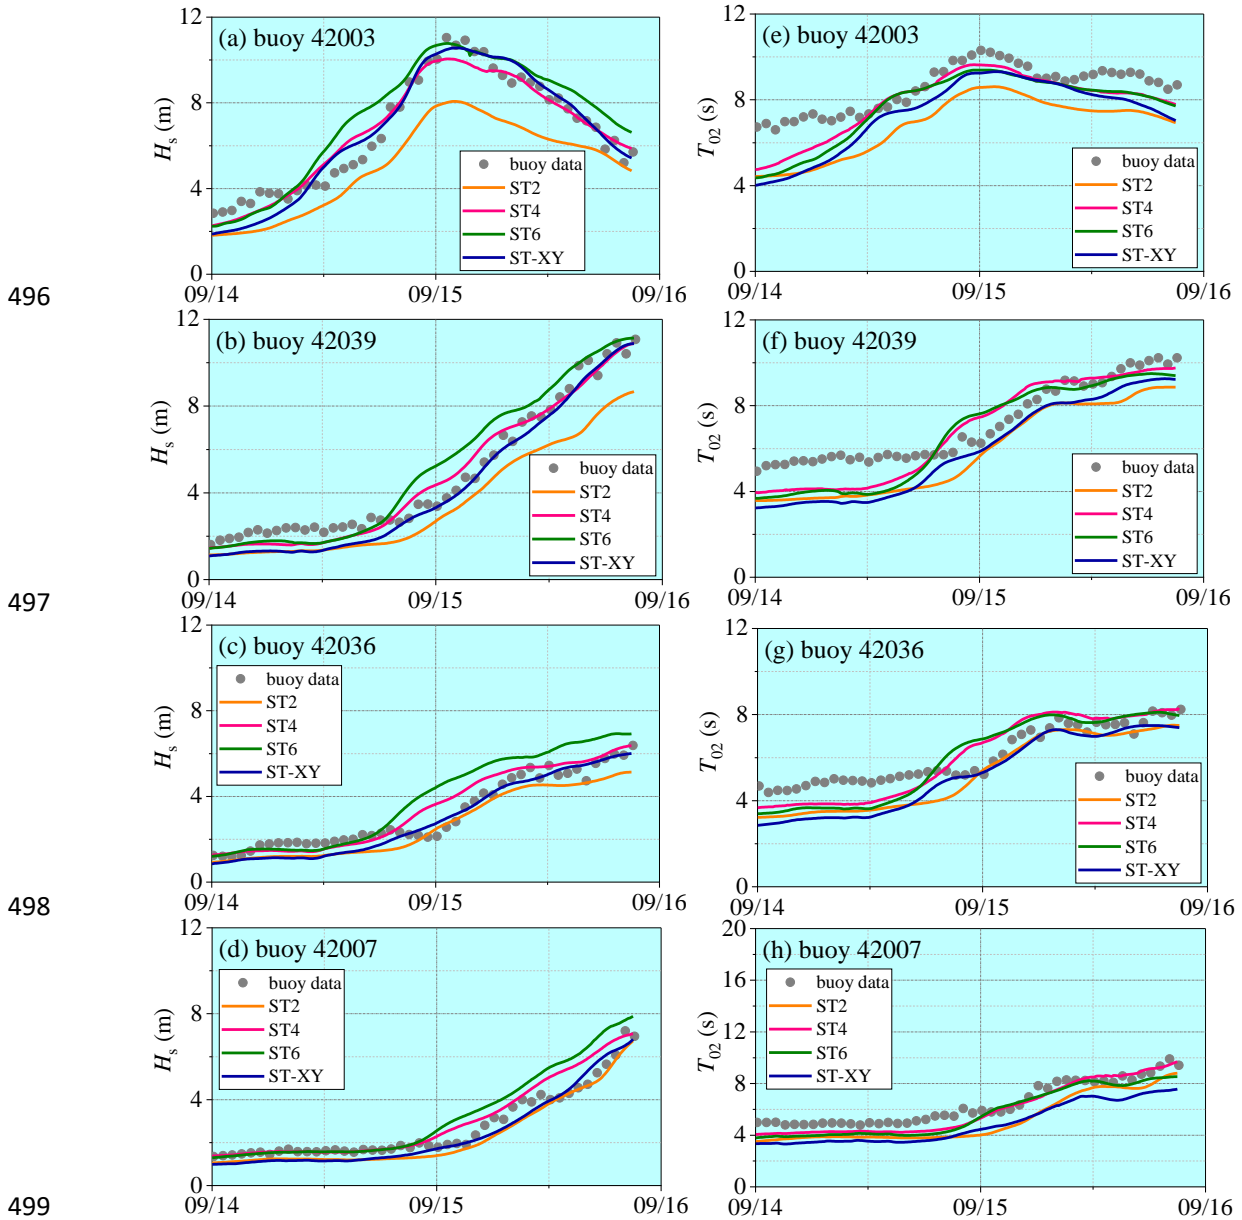

471

472 Figure 10. The computational domain. Tracks of hurricanes are shown with solid lines. The
 473 NDBC buoys are marked by triangles. Water depth at the locations of buoys 42003, 42039,
 474 42036 and 42007 are 3265 m, 281 m, 50.9 m and 14.9 m, respectively.

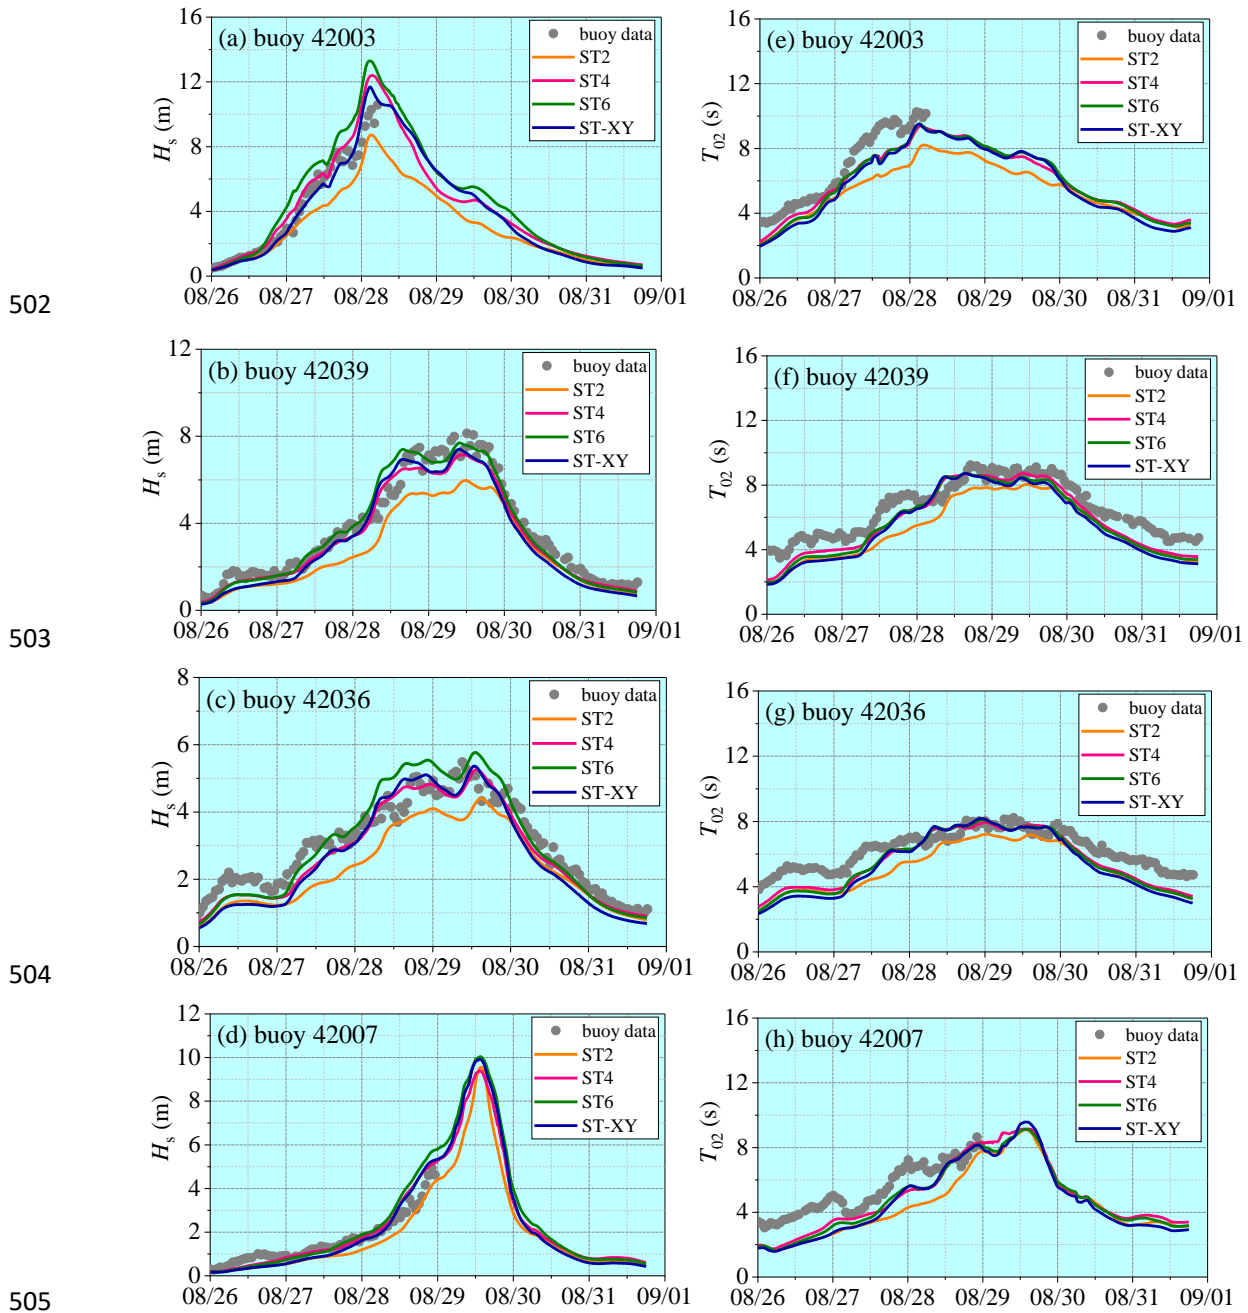

475 4.3 Comparison of wave parameters

476 The model results on the time variations of the significant wave height H_s and the mean
 477 wave period T_{02} at the locations of the buoys during Hurricane Ivan and Hurricane Katrina
 478 are shown in Figures 11 and 12, respectively. The observed data are also plotted for
 479 comparison. It can be seen that the significant wave height H_s obtained with the ST-XY
 480 option agrees fairly well with the buoy data and performs better than the ST2 and ST6
 481 options. The peak value and peak time of the significant wave height are accurately
 482 represented. In comparison, the significant wave height H_s is obviously overestimated by the
 483 ST6 option but underestimated by the ST2 option. The ST4 option performs also very well,
 484 but still show some underestimation of the peak values of H_s (as shown in Figures 11a and
 485 12a) and some overestimation of H_s before it reaches its maximum value (as shown in
 486 Figures 11b-d). The numerical results for the mean wave period T_{02} are shown to be
 487 generally less accurate than those for the significant wave height H_s , especially during the
 488 period before and after the hurricane event. A possible reason is that the total wave energy is
 489 paid more attention when formulating source terms of the wave model while the statistical
 490 laws for wave period are usually less accurate under relatively calm sea conditions. Note
 491 that an underestimation of T_{02} is evident, but the peak values of T_{02} are still reasonably

492 simulated. The mean absolute error (MAE) and root mean square error (RMSE) for each
 493 hurricane event are shown in Tables 1 and 2. It is demonstrated that the ST-XY has
 494 outstanding performance on H_s with obviously smaller MAE and RMSE values. The
 495 performance of ST4 is also satisfactory as compared to ST2 and ST6.

512

513 4.4 Comparison of wave spectra

514 For the detailed description of a wave spectrum, the peak value E_p , the peak
515 frequency f_p of the spectrum as well as its mean square slope M_s are defined to describe
516 the frequency spectrum; the dominant wave propagation direction θ_m , the mean wave
517 propagation direction $\bar{\theta}$ and the directional spreading width $\Delta\theta$ are defined to describe
518 the directional spectrum. In particular,

$$519 \quad E_p = \max \left(\int_0^{2\pi} E f, \theta d\theta \right) \quad (14)$$

$$520 \quad M_s = \iint k^2 E f, \theta df d\theta \quad (15)$$

521
$$E \theta_m = \max \int E f, \theta df \quad (16)$$

522
$$E \theta_e \geq 0.1 \max \int E f, \theta df \quad (17)$$

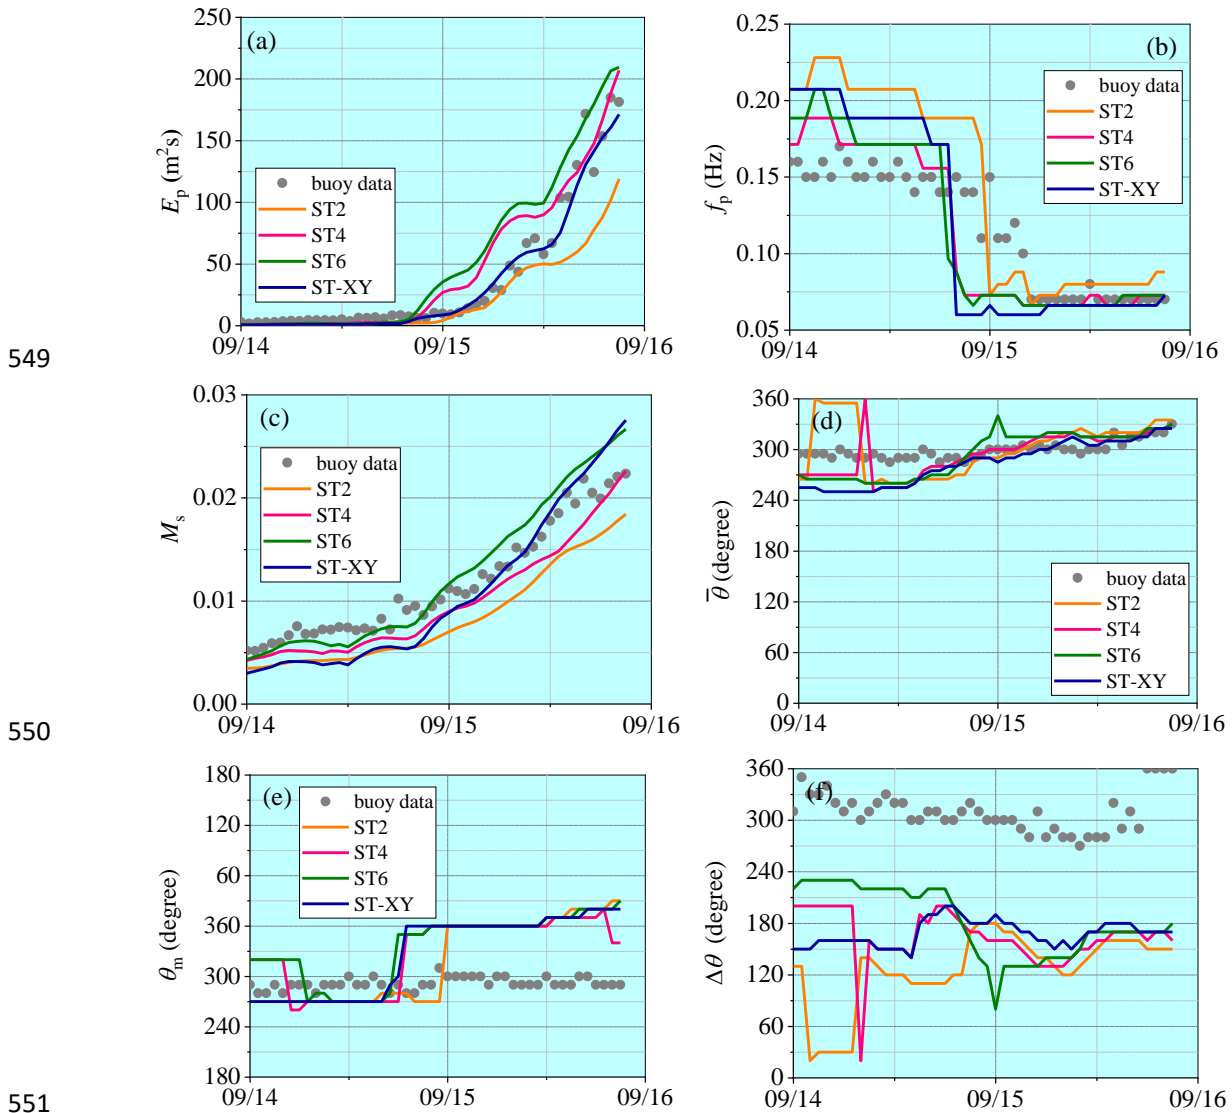

523
$$\bar{\theta} = \frac{1}{2} \theta_{e1} + \theta_{e2} \quad (18)$$

524
$$\Delta\theta = \theta_{e2} - \theta_{e1} \quad (19)$$

525 where, E_p is the peak value of the frequency spectrum, f_p is the corresponding peak
 526 frequency; M_s is the mean square slope of frequency spectrum, representing the effect of
 527 high-frequency wave components; $E \theta_m$ is the peak of the directional spectrum and θ_m
 528 is the corresponding direction, called the main wave direction; θ_e is called the efficient
 529 wave direction beyond which the wave energy is below 10% of the peak value of the
 530 directional spectrum; θ_{e1} and θ_{e2} are the lower and higher limits of θ_e ; $\bar{\theta}$ is the mean
 531 wave propagation direction while $\Delta\theta$ is the directional range of the effective wave
 532 propagation.

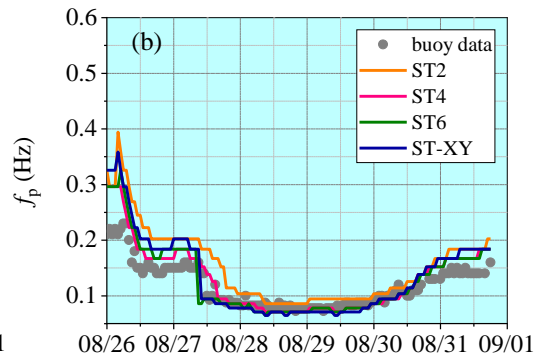

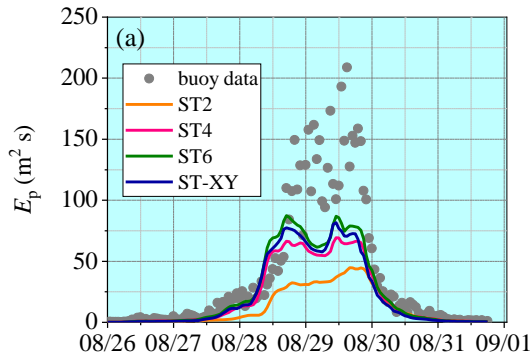

533 Comparison of the computed wave spectra with observations is made at the locations of
 534 buoys 42039 and 42036, where a relatively complete data series have been recorded during
 535 both hurricane events. Variations of the spectral wave parameters in the deep-water
 536 condition (at buoy 42039) are presented in Figures 13 and 14 while those in the shallow
 537 water condition (at buoy 42036) are presented in Figures 15 and 16. Accuracy of the
 538 numerical results for the peak spectrum value E_p is quite similar to that for the
 539 representative wave parameters such as H_s . The result obtained with the ST-XY option can
 540 catch the extreme wave energy condition very well, while the ST6 option always
 541 overestimate and the ST2 option underestimate it. The result obtained with the ST4 option
 542 overestimates E_p under the moderate wind conditions before the extreme events. The
 543 numerical results for the peak frequency f_p agrees with observations well during both
 544 hurricane events. M_s is also satisfactorily simulated, which means that the high frequency
 545 part of the wave spectrum is well described by the numerical model. It may be necessary to
 546 point out that, different from the results for the representative wave parameters, the peak of

547 E_p may not be correctly represented by any package of the source terms under our
 548 consideration in some cases, as shown in Figure 14a.

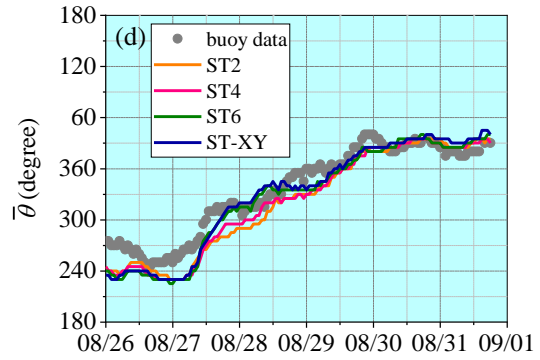

552 Figure 13. Comparisons of wave spectral parameters with observations at buoy 42039
 553 during Hurricane Ivan. (a) spectrum peak value; (b) peak frequency; (c) mean square slope;

557

558

559 Figure 14. Comparisons of wave spectral parameters with observations at buoy 42039
560 during Hurricane Katrina. (a) spectrum peak value; (b) peak frequency; (c) mean square
561 slope; (d) mean wave propagation direction; (e) main wave propagation direction; (f) wave
562 propagation spread width.

566 Figure 15. Comparisons of wave spectral parameters with observations at buoy 42036
 567 during Hurricane Ivan. (a) spectrum peak value; (b) peak frequency; (c) mean square slope;
 568 (d) mean wave propagation direction; (e) main wave propagation direction; (f) wave
 569 propagation spread width.

573 Figure 16. Comparisons of wave spectral parameters with observations at buoy 42036
 574 during Hurricane Katrina. (a) spectrum peak value; (b) peak frequency; (c) mean square
 575 slope; (d) mean wave propagation direction; (e) main wave propagation direction; (f) wave
 576 propagation spread width.

577 It is also demonstrated that the numerical results for the main wave propagation
 578 direction and the mean wave propagation direction obtained with the ST-XY option and
 579 other source-term options are all equally good. However, the numerical result for the
 580 directional range of the effective wave propagation is obvious narrower than observed one.
 581 This, however, may not be an error of the numerical model since the directional range of the
 582 effective wave propagation depends significantly on the methods employed (Earle et al.,

583 1999; Kim et al., 1995). In this study, Longuet-Higgins' method (Longuet-Higgins et al.,
584 1963) is used to build the directional wave spectrum from observed data. This method
585 always leads a broader directional spectrum than other methods with the same parameters
586 (Earle et al. (1999)'s Figure 2).

587 Waves under hurricane condition break more frequently and severely than under
588 normal condition due to high wind speed and rapidly transforming wind direction, leading
589 to a relatively large amount of wind energy input into the breaking wave components and
590 also an increased total wind energy input. On the other hand, severe wave breaking under
591 hurricane condition also causes high wave energy dissipation. Therefore, a careful
592 consideration of the effect of wave breaking is very important for simulation of wave
593 development under the action of tropical cyclones. Since evolution of the wave spectrum
594 depends on the net effect of the wind energy input and the wave energy dissipation, while it
595 is difficult to identify a decrease of wind energy input from an increase of wave energy
596 dissipation, particularly under extreme sea state, we emphasize that the wind energy input
597 proposed by Xu and Yu (2020) and the wave energy dissipation extended from that of
598 Ardhuin et al. (2010) must be considered as a set.

599 **5. Conclusion**

600 This study is aimed to evaluate the performance of the improved formulas for the wind
601 energy input and the wave energy dissipation, i.e., the ST-XY source-term option. The
602 numerical results are obtained with the coupled AWBLM-WWIII model. Both
603 duration-limited waves under idealized conditions and hurricane-generated waves, in both
604 deep and shallow waters are studied. The standard source-term packages of ST2, ST4 and
605 ST6 embedded in WWIII are chosen for comparison. Detailed comparisons are made for not
606 only the representative wave parameters, including the significant wave height, the mean
607 wavelength and the mean wave period, but also the characteristic parameters for the
608 frequency spectrum and the directional spreading function. The effect of breaking on ocean
609 wave modeling is fully discussed.

610 The numerical results show that the ST-XY source-term package performs better than

611 other standard options in general. At the early wave-development stage, the ST-XY option
612 leads to a better agreement of the computed wave energy with the empirical results while
613 other source-term options all tend to underestimate the wave energy. At the equilibrium
614 stage, the results obtained with the ST-XY option approaches the Pierson-Moskowitz limit
615 while ST2 option significantly underestimates the wave energy. The ST-XY option is also
616 effective for ocean wave modeling under both deep- and shallow- water conditions and
617 gives results in good agreement with field data. For hurricane-generated waves, model
618 results obtained with the ST-XY option agrees well with the buoy data and are obviously
619 better than those obtained with other source-term options. On the other hand, the ST6 option
620 often overestimates wave energy while ST2 option leads to an obvious underestimation. The
621 ST4 option performs fairly well but still show some underestimation of the peak value of
622 significant wave height and some overestimation of the significant wave height before its
623 peak value is achieved.

624 Wave breaking significantly affect ocean wave modeling, especially at younger wave
625 ages and in shallower waters. At the early wave-development stage, a significant part of the
626 peak wind energy input takes place under breaking condition, and the proportion decreases
627 gradually as the wave development continues. In shallow waters, the peak value of wind
628 energy input taking place under breaking conditions are always higher than that under
629 non-breaking conditions throughout the early wave-development stage to the equilibrium
630 stage.

631 In summary, the improved formula of Xu and Yu (2020), which includes both breaking
632 effect and the effect of air-flow separation on the leesides of steep wave crests in a
633 consistent way, has a satisfactory performance within the coupled AWBLM-WWIII model.
634 It is physics-based and is verified to be effective for ocean wave modeling under both
635 moderate and extreme wind conditions, at all wave-development stages, and in deep to
636 shallow waters, thus has a broad applicability.

637 **Competing interests**

638 The authors declare that there is no conflict of interest.

639 **Authors' contributions**

640 Y. Xu and X. Yu conceived of the presented idea. Y. Xu performed the computations. X.
641 Yu supervised the project. Both authors discussed the results and contributed to the final
642 manuscript.
