

10

## Abstract

11 Accurate description of the wind energy input into ocean waves is crucial to ocean  
12 wave modeling and a physics-based consideration on the effect of wave breaking is  
13 absolutely necessary to obtain such an accurate description. This study evaluates the  
14 performance of an improved formula recently proposed by Xu and Yu (2020), who took into  
15 account not only the effect of breaking but also the effect of air-flow separation on the  
16 leeside of steep wave crests in a reasonably consistent way. Numerical results are obtained  
17 through coupling an enhanced atmospheric wave boundary layer model with the ocean wave  
18 model WaveWatch III (v5.16). The coupled model has been extended to be valid in both  
19 deep and shallow waters. Duration-limited waves under controlled normal conditions and  
20 storm waves under practical hurricane conditions are studied in details to verify the  
21 improved model. Both the representative wave parameters and the parameters characterizing  
22 the wave spectrum are discussed. It is shown that the improved source-term package for the  
23 wind energy input and the wave energy dissipation leads to more accurate results under all  
24 conditions. It performs evidently better than other standard source-term options of ST2, ST4  
25 and ST6 embedded in WaveWatch III. It is also demonstrated that the improvement is  
26 particularly important for waves at their early development stage and waves in shallow  
27 waters.

## 30 1. Introduction

31 Accurate modeling of ocean waves depends straightforwardly on a correct formulation  
32 of the wind energy supply to the waves through the ocean surface as well as the wave  
33 energy dissipation within the ocean surface layer, and eventually on a thorough  
34 understanding to the physics underlying these two dynamic processes. The wind energy  
35 input supports the generation and growth of ocean waves, while the wave energy dissipation  
36 always occurs owing not only to the viscous property of the fluid but also to the effects of  
37 turbulent mixing and multiphase interaction that take place in the boundary layer at both  
38 sides of the air-sea interface. In the past decades, a tremendous number of research efforts  
39 have been made to enhance our understanding on the phenomena of wind energy input into  
40 ocean waves and the dissipation of ocean surface waves due to various mechanisms.  
41 However, a comprehensive integration of the accumulated knowledge, particularly those  
42 developed under extreme conditions in shallow waters, does not seem to have been  
43 satisfactorily achieved up to date.

44 Janssen (1989; 1991; 2004) proposed the most classical formula for the wind energy  
45 input based on the resonance theory of Miles (1957; 1965), in which the wind drag as a  
46 deterministic function of the roughness height of the ocean surface is a critical parameter.  
47 Hasselmann et al. (1973) obtained an expression for the wind energy input by solving the  
48 wave energy equation and then calibrating parameters with field data from the joint North  
49 Sea wave project (JONSWAP). Snyder et al. (1981) and Donelan et al. (2006) conducted  
50 field experiments in the Bight of Abaca, Bahamas, and Lake George, Australia, and included  
51 more physics in their formula for the wind energy input. Badulin et al. (2007) and Zakharov  
52 et al. (2012; 2017) proposed a new method to establish a theory for the wind energy input  
53 by considering the weakly turbulent law for wind-wave growth. In spite of these important  
54 achievements, the wind energy input is still not yet satisfactorily formulated, basically due  
55 to complexity of the phenomenon as well as the physics underlying the phenomenon.

56 Researchers have found substantial differences between wind energy input through  
57 ocean surfaces with and without wave breaking (Banner and Melville, 1976). Data collected  
58 during the AUSWEX field campaign at Lake George, Australia (Babanin et al., 2007)

59 showed that under a severe breaking condition, the wind energy input will increase to about  
60 2 times of that under a relevant non-breaking condition. Although the important effects of  
61 wave breaking as well as short-wave dissipation on wind energy input have been well  
62 understood (Janssen, 1989, 1991; Makin and Kudryavtsev, 1999; Hasselmann et al., 1973;  
63 Babanin et al., 2007), it is only until recent that Xu and Yu (2020) proposed a formula to  
64 effectively include these effects. Xu and Yu (2020)'s formula takes into consideration both  
65 the breaking effect and the effect of air-flow separation on the leeside of steep wave crests  
66 in a reasonably consistent way. Despite of its physics-based nature, a further evaluation of  
67 its performance in practical and more complicated wind wave conditions, however, is still  
68 necessary.

69 It is generally believed that, among the total wind energy transferred into the ocean  
70 waves, a part is absorbed by the long-wave components to support wave growth while an  
71 even larger part is received by the short-wave components and quickly dissipated due to  
72 fluid viscosity, wind shear on the ocean surface and the turbulence effect related to wave  
73 breaking (Csanady, 2001; Jones and Toba, 2001). Formulation of the wave dissipation,  
74 however, is very difficult and the available suggestions in the literature are rather  
75 controversial (Cavaleri et al., 2007). The earliest wave dissipation model is known to be the  
76 probabilistic breaking model originally presented by Longuet-Higgins (1969) and then  
77 improved by Yuan et al. (1986). Hasselmann (1974) proposed the whitecap model based on  
78 a mathematical formulation of the negative work done by the downward whitecap pressure  
79 on the upward wave motion. Phillips (1985) and Donelan and Pierson (1987) proposed the  
80 quasi-saturation model by assuming a local equilibrium relationship among wind energy  
81 input, nonlinear transfer and wave dissipation. Polnikov (1993) preferred the turbulence  
82 dissipation model which relates the loss of wave energy to the dissipation of turbulence  
83 kinetic energy. In addition to the theoretical studies, a significant number of experimental  
84 investigations have also been carried out (Phillips et al., 2001; Melville and Matusov, 2002;  
85 Donelan, 2001; Hwang, 2005). Based on the data measured at Lake George, Australia,  
86 Bananin and Young (2005) established an empirical model, in which the concept of  
87 cumulative effect is introduced so that the contribution of low-frequency wave motion to

88 breaking of high-frequency waves can be taken into account. It may be necessary to point  
89 out that most of the experimental studies are supported only by limited data.

90 WaveWatch III (WWIII), a successful third-generation wave model, has been widely  
91 used for simulating ocean waves in both deep and shallow waters. With great efforts made  
92 by scientists around the world (Ardhuin et al., 2010; Zieger et al., 2015), parameterizations  
93 of the source terms in WWIII have been well calibrated under various conditions to achieve  
94 satisfactory results for evolution of an ocean wave spectrum. Under severe wave conditions,  
95 however, their accuracy is often unsatisfactory and the wave energy is underestimated even  
96 with an optimal choice of the parameters (Cavaleri et al., 2020; Campos et al., 2018;  
97 Mentaschi et al., 2015). Meanwhile, researchers found that the directional wave spectrum  
98 has been sometimes very poorly simulated even when the significant wave parameters are  
99 accurately represented (Fan and Rogers, 2016). Stopa et al. (2016) believed that all wave  
100 models have difficulty in describing the directional spread of waves. Although modelers  
101 usually tend to attribute the numerical error to the inaccuracy of the wind data or topography  
102 data, we must admit that imperfection of the source term parameterization, especially under  
103 severe wave conditions, is also one of the main reasons.

104 In this study, improved formulas for the wind energy input and the wave energy  
105 dissipation are embedded into the WWIII version 5.16, though it may also be applied to  
106 other ocean wave models. The enhanced atmospheric wave boundary layer model (AWBLM)  
107 (Xu and Yu, 2021) is also coupled to ensure a more accurate wind stress evaluation at high  
108 wind speed and in finite water depth. The performances of the improved formulas are  
109 evaluated under both idealized wind conditions and real extreme conditions. Attention is  
110 also paid to their differences in deep- and shallow-waters. The structure of the paper is  
111 arranged as follows. The improved formulation as well as the framework of the coupled  
112 AWBLM-WWIII model are described in Section 2. Model verification under controlled  
113 conditions is presented in Section 3, while model verification under extreme wind  
114 conditions is presented in Section 4. Section 5 is a summary of conclusions.

## 115 2. Model Description

### 116 2.1 Coupled AWBLM-WWIII Model

117 The ocean wave model WaveWatch III numerically solves the energy conservation  
118 equation for wave action density spectrum (WW3DG, 2016):

$$119 \quad \frac{DN}{Dt} = \frac{S}{\omega} \quad (1)$$

$$120 \quad S = S_{in} + S_{ds} + S_{nl} \quad (2)$$

121 where  $N(\omega, \theta)$  is the wave action density spectrum;  $\omega$  is the relative frequency;  $S$  is  
122 the source/sink term given by Eq. (2). In general, the source term  $S$  must represent three  
123 different mechanisms: the wind energy input into waves  $S_{in}$ , the wave energy dissipation  
124  $S_{ds}$ , the nonlinear wave-wave interaction  $S_{nl}$ . Although  $S_{in}$  and  $S_{ds}$  represent different  
125 physical processes, they should be considered and calibrated interrelatedly since the net  
126 effect of these two sources rather than each of them can be more accurately measured on  
127 many occasions and it is the net effect that governs the growth/decay of the ocean waves.  
128  $S_{nl}$  plays a key role in the evolution of wave spectrum shape and may, at least theoretically,  
129 be evaluated through correctly solving the nonlinear transfer integrals. Note that, in shallow  
130 waters, the wave energy dissipation must include those due to bottom friction and  
131 depth-induced breaking, denoted by  $S_{dsf}$  and  $S_{dsb}$ , respectively, in addition to that due to  
132 whitecaps, denoted by  $S_{dsw}$ , i.e.,  $S_{ds} = S_{dsf} + S_{dsb} + S_{dsw}$ . It may also be worthwhile  
133 mentioning that an accurate evaluation of the nonlinear interaction effect is surprisingly  
134 difficult for the high-frequency wave components, particularly in shallow waters. Therefore,  
135 it is frequently suggested to apply a semi-empirical theory for evaluating  $S_{nl}$ , i.e., let  
136  $S_{nl} = S_{nl4} + S_{nl3}$ , where  $S_{nl4}$  and  $S_{nl3}$  are expressed as functions of the wave frequency  
137 as well as the wave direction, and represent the quartet and triad wave interactions, which  
138 play dominant roles in deep and shallow waters, respectively.

139 In order to accurately simulate ocean waves under moderate to severe wind conditions,  
140 and from deep to shallow water conditions, an advanced atmospheric wave boundary layer  
141 model (AWBLM) must be coupled into WWIII for a dynamic evaluation of the wind stress.

142 The AWBLM applicable for this purpose is well described in Xu and Yu (2021), which may  
143 take effects of both ocean surface state and water depth into consideration, and has certain  
144 advantages compared to a simple quadratic formula for the wind stress. In the coupled  
145 model, the source terms are treated in the following way. Quartet-wave interaction is  
146 computed with the standard discrete interaction approximation (DIA). Note that, though it  
147 may bring some uncertainty into the numerical results for nonlinear effects, the DIA method  
148 is still widely employed in practical applications due to its minimum requirement on the  
149 computational efforts (Liu et al., 2017; Stopa et al., 2015; Ardhuin et al., 2010). Triad-wave  
150 interaction is evaluated with the Lumped Triad Approximation model (Eldeberky, 1996).  
151 The bottom friction effect is described by the simple model of JONSWAP (Hasselmann et  
152 al., 1973). The Battjes and Janssen (1978) parameterization is employed to represent the  
153 effect of depth-induced breaking. The parameters included in all source terms except for  
154 those with special emphases follow the default setting. The wind energy input and the wave  
155 energy dissipation are considered as a package in this study. WWIII provides four typical  
156 options of this package, i.e., ST2, ST3, ST4, ST6, among which ST3 and ST4 are based on  
157 the same formulation of Janssen (2004) for the wind energy input. Since ST4 has been  
158 frequently reported to have a better performance than ST3 (Stopa et al., 2016; Beyá et al.,  
159 2017; Liu et al., 2017), the ST3 option is neglected in this study. The standard options are  
160 carefully compared with the improved model proposed by the present authors (Xu and Yu,  
161 2020).

## 162 2.2 Improved Model of Xu and Yu (2020)

163 The wind energy input in the improved model of Xu and Yu (2020), hereafter referred as  
164 ST-XY option, is expressed by

$$165 \quad S_{\text{in}}(k, \theta) = \frac{\rho_a}{\rho_w} \omega \gamma_g(k, \theta) E(k, \theta) \quad (3)$$

$$166 \quad \gamma_g(k, \theta) = a \left[ b_T \lambda G' + (1 - b_T) G \right] W^2 \sqrt{B_n} \quad (4)$$

$$167 \quad W = \max \left( 0, \frac{U_{10}}{c_p} \cos(\theta - \theta_a) - 1 \right) + a_0 \min \left( 0, \frac{U_{10}}{c_p} \cos(\theta - \theta_a) - 1 \right) \quad (5)$$

$$168 \quad B_n(k) = A(k) \int_0^{2\pi} k^3 E(k, \theta') d\theta' \quad (6)$$

$$169 \quad b_T(k) = 89.5 \left( \sqrt{B_n(k)} - 0.0223 \right)^2 \quad (7)$$

$$170 \quad G = 2.8 - 1.0 \left[ 1 + \tanh \left[ 10 \sqrt{B_n} \left( \frac{U_{10}}{c_p} \cos(\theta - \theta_a) - 1 \right)^2 - 11 \right] \right] \quad (8)$$

171 where  $\rho_a$  is the density of air;  $\rho_w$  is the density of water;  $\omega$  is radian frequency;  $k$  is  
 172 the wavenumber, which is related to  $\omega$  through the dispersion relation;  $\theta$  is the wave  
 173 direction;  $E(k, \theta)$  is the directional wave energy spectrum;  $\gamma_g(k, \theta)$  is the wave growth  
 174 rate;  $c_p$  is the celerity of the wave with peak frequency;  $U_{10}$  is the wind speed at the 10 m  
 175 level above the ocean surface;  $\theta_a$  is the wind direction. Note that the basic form of Eq. (3)  
 176 follows the conventional assumption that  $S_{in}$  is proportional to the directional wave  
 177 spectrum. However, the most crucial factor in  $S_{in}$ , i.e., the wave growth rate  $\gamma_g$  is  
 178 formulated to represent the effect of various physical processes. Although  $\gamma_g$  is essentially  
 179 governed by the relative wind speed and the mean steepness of the surface waves, it is  
 180 considered to be essentially different when wave breaking does or does not occur, and is  
 181 thus expressed as a weighted average of the different multipliers corresponding to breaking  
 182 and non-breaking conditions with the breaking probability  $b_T$  being the weight. The  
 183 relative wind speed is expressed by Eq. (5), where deflection of the wind direction from the  
 184 wave direction is fully considered. It may be necessary to point out that the contribution of  
 185 the inverse wind to energy input is reduced by a factor of  $a_0 = 0.45$  following Liu et al.  
 186 (2017). Under the non-breaking condition, a separation coefficient  $G$  is introduced to  
 187 represent the ‘shelter effect’ due to airflow separation at the lee side of high wave crests  
 188 following Donelan et al. (2006). When wave breaks, the ‘shelter effect’ disappears and  $G$   
 189 reduces to its maximum value  $G' = 2.8$ . Since wave breaking has an effect of intensifying  
 190 wind energy input, we introduce an amplification factor  $\lambda$ , and let  $\lambda = 2.0$ , also  
 191 following previous studies. It may also be necessary to mention that the wave steepness is  
 192 related to the saturated wave spectrum  $B_n(k)$ , as expressed by Eq. (6), where  $A(k)$  is a

193 measure of the directional spectrum width. In general, the wind energy input is positive, but  
 194 it may become negative when a strong swell is in presence and the wind speed is smaller  
 195 than the wave celerity or when the direction of wind is significantly deflected from the wave  
 196 direction.

197 The advantage of the wind energy input in the improved model of Xu and Yu (2020) is  
 198 its direct representation of the underlying physics. Based on the field observations of both  
 199 Donelan et al. (2006) and Babanin et al. (2007), the wind energy input into waves under  
 200 severe conditions is a very complicated process, since random waves may break and may  
 201 not break depending on the instantaneous local wave steepness. For non-breaking waves,  
 202 air-flow separation occurs on the leeside of wave crests, and the wind energy input reduces.  
 203 For breaking waves, the wind energy input is significantly larger due to breaking induced  
 204 mixing. The improved model of Xu and Yu (2020) fully considers these two effects and,  
 205 consequently, should be more suitable for the description of severe waves.

206 Since the ocean wave development depends actually on the net energy gain in the ocean  
 207 surface layer and it is sometimes very difficult to identify if some amount of wind energy is  
 208 transferred into the ocean waves and then dissipated or it is dissipated within the  
 209 atmospheric boundary layer and not received by the ocean at all,  $S_{in}$  and  $S_{ds}$  must then  
 210 be considered as a package. In other words, formulation of the dissipation term should be  
 211 based on a relevant definition of the wind energy input. In this study, we follow the wave  
 212 dissipation model of Ardhuin et al. (2010) for the whitecap effect. The semi-empirical  
 213 dissipation model of Ardhuin et al. (2010) can be expressed as (see also Leckler et al., 2013)

$$214 \quad S_{dsw} = S_{dsn} + S_{dsc} \quad (9)$$

$$215 \quad S_{dsn} = \xi_n B_r^{-2} \omega \left\{ \delta_d \max[B(k) - B_r, 0]^2 + (1 - \delta_d) \max[B'(k, \theta) - B_r, 0]^2 \right\} E(k, \theta) \quad (10)$$

$$216 \quad S_{dsc} = -1.44 \xi_c \left\{ \int_0^{r_c k} \int_0^{2\pi} \max[\sqrt{B(k', \theta')} - \sqrt{B_r}, 0]^2 \Delta c_p d\theta' dk' \right\} E(k, \theta) \quad (11)$$

217 where,  $\xi_n$  and  $\xi_c$  are empirical constants;  $\delta_d$  is a factor introduced to weight the  
 218 isotropic part and direction-dependent part;  $r_c$  is the minimum ratio of the wavenumber

219 that will wipe out the short waves. The saturation spectrum  $B_n(k)$  is defined in the same  
220 way as before and the directional saturation spectrum  $B_n'(k, \theta)$  is defined by

$$221 \quad B_n'(k, \theta) = \int_{\theta - \Delta_\theta}^{\theta + \Delta_\theta} k^3 \cos^2(\theta - \theta') E(k, \theta') d\theta' \quad (12)$$

222 The threshold of  $B_n(k)$  is denoted by  $B_r$ . Note that Eqs. (9), (10) and (11) are based the  
223 assumption that wave dissipation consists of an inherent effect and a cumulative effect, both  
224 are proportional to the directional wave spectrum. In shallow waters, dissipations due to  
225 bottom friction and depth-induced breaking are formulated following Xu and Yu (2021).

### 226 2.3 Standard Models

227 Known reliable formulas for the wind energy input and the wave energy dissipation  
228 have been embedded in WWIII. Among all, the following options, which have been widely  
229 preferred on different occasions, are chosen for comparison in this study.

230 **(1) ST2 option.** This package, originally proposed by Tolman and Chalikov (1996),  
231 consists of the wind energy input formula of Chalikov and Belevich (1993) and Chalikov  
232 (1995) as well as a relevant wave energy dissipation model. The dissipation model  
233 emphasizes the different mechanisms of dissipation for low- and high-frequency waves. The  
234 expression for low-frequency waves is based on an analogy to energy dissipation due to  
235 turbulence, while that for high-frequency waves is purely empirical. A linear combination of  
236 these two expressions then represents the total dissipation. It has been reported that this  
237 wind energy input formula may need to be filtered using a special technique when a strong  
238 swell is in presence (Tolman, 2002). For the purpose of comparison, the default setting of  
239 parameters in this study follows Tolman (2002), who selected this package in WWIII for a  
240 global ocean wave modeling and obtained satisfactory results.

241 **(2) ST4 option.** This package consists of the wind energy input formula of Janssen  
242 (2004), which is based on the wave growth theory of Miles (1957), and the wave energy  
243 dissipation model of Ardhuin et al. (2010). The dissipation model appears as the summation  
244 of an inherent part and a cumulative part. All parameters are determined following Ardhuin  
245 et al. (2010).

246 **(3) ST6 option.** This package consists of the formulas for wind energy input and wave

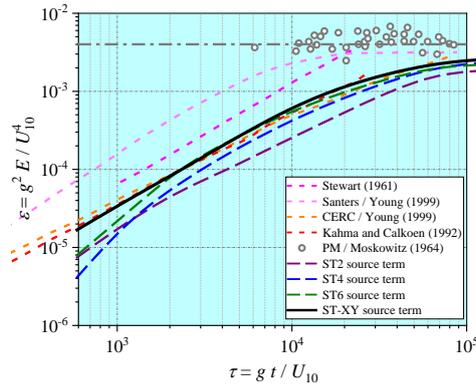

247 energy dissipation due to whitecaps which fit the field data obtained at Lake George,  
248 Australia (Donelan et al., 2006; Rogers et al., 2012). A sink term due to negative wind  
249 energy input is considered for inverse winds. The dissipation due to whitecaps is expressed  
250 as the sum of an inherent part, which is proportional to wave spectrum, and a cumulative  
251 part in terms of the integral properties of the wave spectrum below a certain value of the  
252 wavenumber.

### 253 **3. Model Verification under Controlled Normal Conditions**

#### 254 **3.1 Duration-limited waves in deep waters**

255 The ideal problem of wave development over the open sea of infinite water depth is  
256 considered. At a given duration, evolution of the directional wave spectrum is simulated  
257 with WWIII considering different choices of the source-term package. The uniform wind  
258 speed at the 10 m height above ocean surface is fixed at a moderate level of 10 m/s.  
259 Sensitivity of the numerical results to the computational time step is also studied. It is  
260 shown that little difference of the numerical results can be observed as the computational  
261 time step takes 30 s, 1 min and 10 min. Therefore, the results obtained with the time step  
262 equal to 10 min are presented in the remaining part of this study.

263 In Figure 1, the wave growth curve, i.e., the relationship between the normalized total  
264 wave energy  $\varepsilon$  and the normalized duration  $\tau$ , computed with different options for the  
265 source terms, is presented and compared with the empirical results available in the literature.  
266 The four empirical growth curves correspond to Stewart's (1961) law, which was originally  
267 presented as tabulated data, Sanders' (1976) law, the CERC (1977) law and Kahma and  
268 Calkoen's (1992) law. The equilibrium value given by the Pierson-Moskowitz spectrum  
269 (Pierson and Moskowitz, 1964), i.e.,  $\varepsilon_{PM} = 3.6 \times 10^{-3}$ , as well as the tabulated values of  
270 Moskowitz (1964) are also plotted.

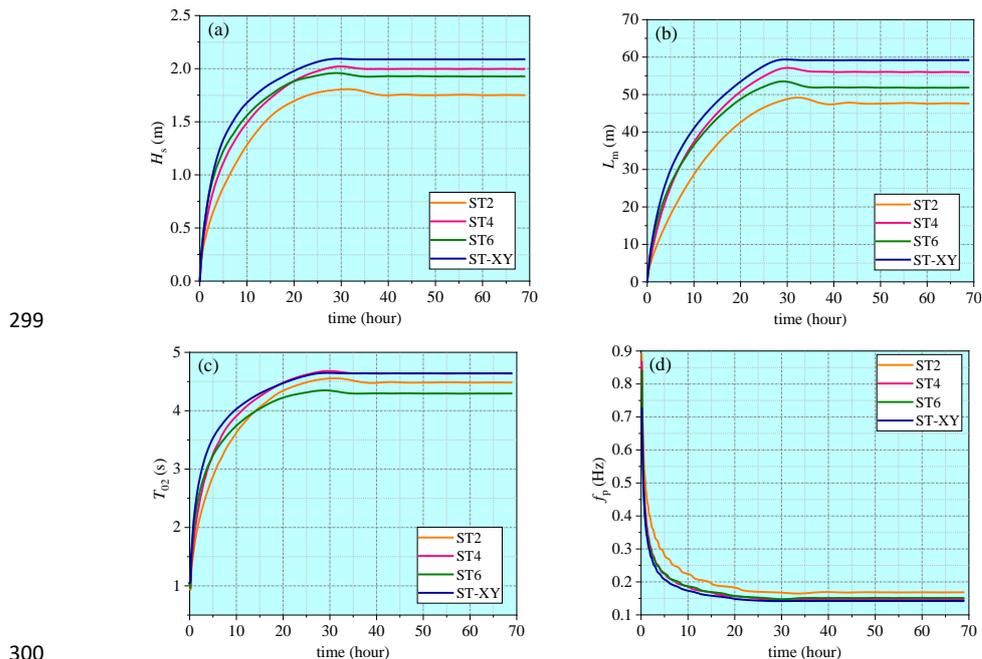

271  
 272 Figure 1. Comparisons of duration-limited growth rate between empirical and computational  
 273 results. Both wave energy and duration are nondimensionalized with  $U_{10}$

274 By comparing the computed wave growth curves with each other and with the empirical  
 275 results as well, it becomes clear that, the WWIII model results with different choices of the  
 276 source-term package are all rather close to the CERC (1977) law and Kahma and CalKoen's  
 277 (1992) law, and also agree with the results of Rogers et al. (2012). At a younger wave age,  
 278 particularly at  $\tau < 2 \times 10^3$ , the ST-XY option performs much better while other  
 279 source-term options underestimate the wave energy significantly. The ST4 option most  
 280 severely underestimate the wave energy at the early stage of wave development. As duration  
 281 increases, the results of the ST6 option approaches those of the ST-XY option. When  
 282 approaching the equilibrium stage ( $10^4 < \tau < 10^5$ ), the numerical results corresponding to  
 283 ST-XY, ST6 and ST4 options all approach the Pierson-Moskowitz limit while the ST2  
 284 option still underestimate the wave energy. In general, the performance of the ST-XY option  
 285 is obviously better.

286 Since the source terms are often formulated in terms of the mean wave parameters,  
 287 evolution of the wave spectrum and development of the mean wave parameters are thus  
 288 interdependent. Therefore, a comparison of the mean wave parameters obtained with  
 289 different choice of the source term options, as presented in Figure 2, is highly meaningful. It  
 290 is demonstrated that the significant wave height  $H_s$  and the mean wavelength  $L_m$  obtained  
 291 with the ST-XY option are slightly greater than the results obtained with other options while  
 292 the ST2 option yields the smallest values. The numerical result of the mean wave period  $T_{02}$

293 obtained with the ST-XY option is the largest at the early wave development stage, but it  
294 becomes almost the same as that obtained with the ST4 option at the equilibrium stage. The  
295 mean wave period  $T_{02}$  obtained with the ST2 option is the smallest at the early  
296 wave-development stage while that obtained with the ST6 option becomes smallest at the  
297 equilibrium stage. The peak frequency  $f_p$  obtained with ST4, ST6 and ST-XY options is very  
298 close to each other, but the ST2 option results in a larger value.

299

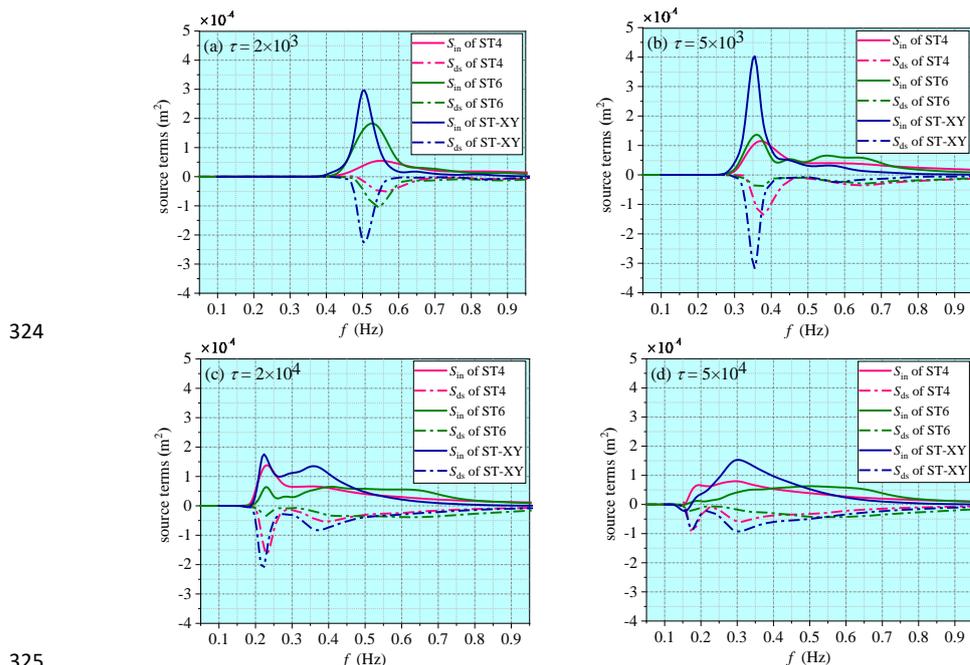

300

301 Figure 2. Comparisons of numerical results for (a) significant wave height  $H_s$ , (b)  
302 wave length  $L_m$ , (c) mean wave period  $T_{02}$  and (d) peak frequency  $f_p$ , obtained with different  
303 choices of the source-term options.

304 A comparison of the computed spectra of the wind energy input and the wave energy  
305 dissipation with different choices of the source-term options is presented in Figure 3. Note  
306 that the spectra obtained with the ST2 option are not presented since they are obviously  
307 underestimated. The numerical results strongly indicate that the wind energy input and the  
308 wave energy dissipation resulted from the same source-term package are correlated, not  
309 only in terms of the peak values but also in terms of the spectral shapes. It is seen that, the

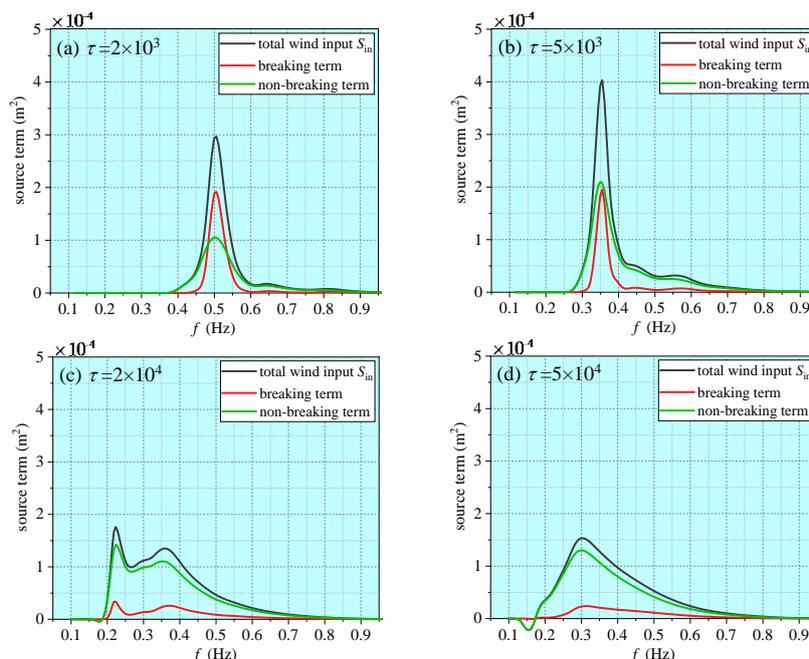

310 wind energy input resulted from the ST-XY option maintains at a higher level than those  
 311 resulted from other options at the early wave-development stage, leading to a faster wave  
 312 growth and higher level of the wave energy at younger wave ages. Relatively concentrated  
 313 unimodal distributions for both the wind energy input and the wave energy dissipation are  
 314 built at the early wave-development stage, no matter which source-term option is adopted.  
 315 As wave development continues, however, the peak frequencies as well as the peak values  
 316 of the spectra decrease while more wind energy is transferred to the higher frequency waves  
 317 and bimodal distributions are formed. At this stage, the peak value of the spectra obtained  
 318 with the ST-XY option is similar to those obtained with the ST6 and ST4 option, while its  
 319 high-frequency part has higher values than those resulted from the ST6 and ST4 options.  
 320 When approaching the fully-developed stage, the wind energy input obtained with the  
 321 ST-XY and ST4 options reaches a peak at relatively low frequency, but the peak obtained  
 322 with the ST6 option appears at a much higher frequency. This is related to whether the  
 323 breaking effect is fully considered when formulating the wind energy input.

324  
 325  
 326 Figure 3. Spectra of the wind energy input and the wave energy dissipation obtained with  
 327 different choices of the source-term package.

328

329

330 Figure 4. Deepwater spectra of wind energy input under breaking and non-breaking  
331 conditions at different wave development stages given by the ST-XY source-term option

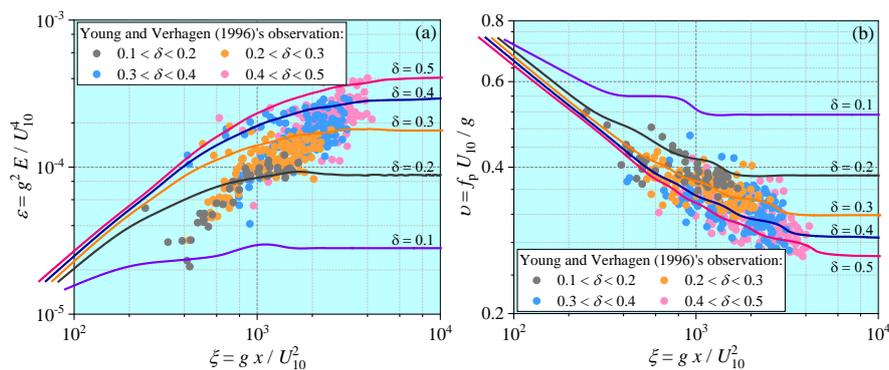

332 A major merit of the improved formula for the wind energy input of Xu and Yu (2020)  
333 is the inclusion of breaking effect and the effect of airflow separation on the leesides of  
334 steep waves. Among the total wind energy input, the portions taking place under breaking  
335 and non-breaking conditions, given by the improved formula of Xu and Yu (2020), are  
336 presented in Figure 4. It is clearly demonstrated that, at the early wave-development stage,  
337 over 60% of the peak wind energy input takes place under the breaking condition. As wave  
338 development continues, the proportion of the peak wind energy input under breaking  
339 conditions decreases rapidly. When approaching the equilibrium stage, only 15% of the peak  
340 wind energy input happens under breaking conditions. The trend suggested by our  
341 numerical results is in very good agreement with the facts reported in previous studies  
342 (Janssen, 1989; Hasselmann et al., 1973). It is thus reasonable to conclude that the ST-XY  
343 option for the wind energy input and the wave energy dissipation successfully integrated the  
344 known information about the effect of breaking on the wind energy input and improved the  
345 performance of the WWIII model, especially at the early wave-development stage when the

346 wave energy has often been underestimated.

### 347 3.2 Duration-limited waves in shallow waters

348 In order to evaluate its performance in nearshore environment, the ST-XY source-term  
 349 option is also applied to the simulation of duration-limited waves in shallow waters. The  
 350 computational conditions are the same as those adopted in the deep-water case except for a  
 351 varying water depth from 5 m to 1 m. The nondimensional water depth  $\delta = gd/U_{10}^2$  then  
 352 varies from 0.5 to 0.1. The computational results are compared with field observations of  
 353 Young and Verhagen (1996), who systematically measured the variations of wave  
 354 parameters and wave spectrum in shallow waters. Since the measured data was provided in  
 355 a fetch-limited manner, the method of Hwang and Wang (2004) is used to transfer the  
 356 duration-limited numerical results to fetch-limited ones for comparison. As demonstrated in  
 357 Figure 5, the numerical results obtained with the ST-XY source-term option in shallow  
 358 waters match well with the field data. As the nondimensional water depth increases from 0.1  
 359 to 0.5, the wave energy increases while the peak frequency decreases. This is well explained  
 360 by the effect of water depth on wave steepness and wave height. Within each range of the  
 361 water depth, the field data basically fall into the relevant two curves resulted from the model.  
 362 This is particularly accurate for the wave energy. Therefore, it may be concluded that the  
 363 improved source-term option of Xu and Yu (2020) is also effective for ocean wave modeling  
 364 under shallow water conditions.

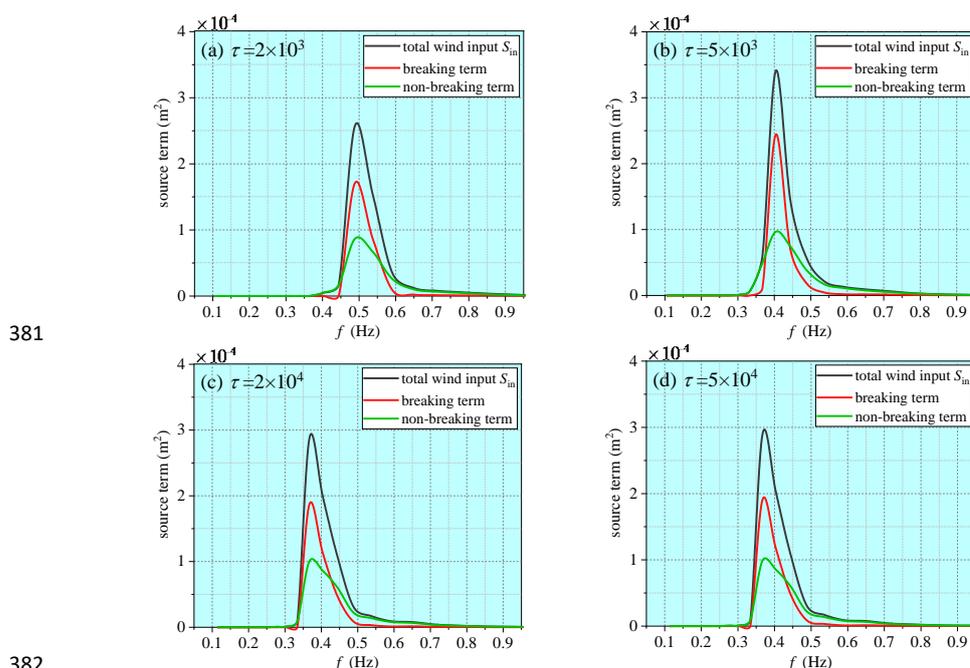

365

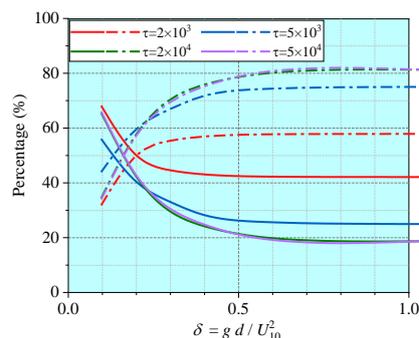

366 Figure 5. Comparisons of (a) fetch-limited growth rate and (b) wave age variation between  
 367 measured and computed results.

368 Intensified breaking is a major feature of the shallow water waves. Correct  
369 representation of the breaking effect in the wind energy input is thus very important for  
370 modeling shallow water waves. Different from the deep-water situation, the peak value of  
371 the wind energy input taking place under breaking conditions are always higher than under  
372 non-breaking conditions all through the early wave-development stage to the equilibrium  
373 stage, as presented in Figure 6. The wind energy input taking place under breaking  
374 conditions remains a high proportion even at the equilibrium stage, indicating a more  
375 frequent breaking in shallow waters. In figure 7, the percentages of the wind energy input  
376 taking place under breaking and non-breaking conditions at different water depths and  
377 different stage of wave development are shown. At each wave development stage, the  
378 percentage taking place under the breaking condition increases as the water depth decreases.  
379 At a given water depth, the breaking effect is more prominent at younger wave age but is  
380 still important at the equilibrium stage.

383 Figure 6. Spectra of wind energy input under breaking and non-breaking conditions resulted  
384 from the ST-XY source-term package at different wave development stages in a water depth  
385 of 2 m

386

387 Figure 7. Variations of the percentage for wind energy input under breaking and  
388 non-breaking conditions. Solid lines are those under breaking condition while dot-dash lines  
389 are those under non-breaking condition. Different colors stand for different wave ages.

#### 390 4. Model Verification under Practical Extreme Conditions

391 Storm waves under hurricane winds are characterized by the general young wave age  
392 and intensive breaking process, due to the extreme wind speed and rapid-changing wind  
393 directions. Therefore, their modeling requires an accurate description of the wind energy  
394 input to represent such characteristics. In this section, the effectiveness of the ST-XY  
395 source-term option is evaluated. Hurricane Ivan (2004) and Hurricane Katrina (2005), both  
396 of which made landfalls at the coastline of Gulf of Mexico, are chosen for our verification  
397 purpose. Hurricanes Ivan and Katrina are both typical, long-lived, category 4-5 tropical  
398 cyclones with well recorded observational data. In fact, Hurricanes Ivan and Katrina have  
399 been extensively modeled and studied in the literature (Wang et al., 2005; Moon et al., 2008;  
400 Fan et al., 2009; Zieger et al., 2015). In addition, since the tracks of the two hurricanes lie in  
401 the same ocean basin, data of the topography, the forced wind and the ocean currents can be  
402 obtained from the same source, and the model settings can also be kept the same.

##### 403 4.1 Available data

404 It is very natural to require possibly most accurate wind data for reliable model results  
405 on ocean wave development (Campos et al., 2018). In this study, we blend the  $H^*$ wind data  
406 (resulted from the Real-time Hurricane Wind Analysis System operated by the Hurricane  
407 Research Division, National Oceanic and Atmospheric Administration) with the ECMWF  
408 (European Centre for Medium-Range Weather Forecasts) data to build the necessary wind

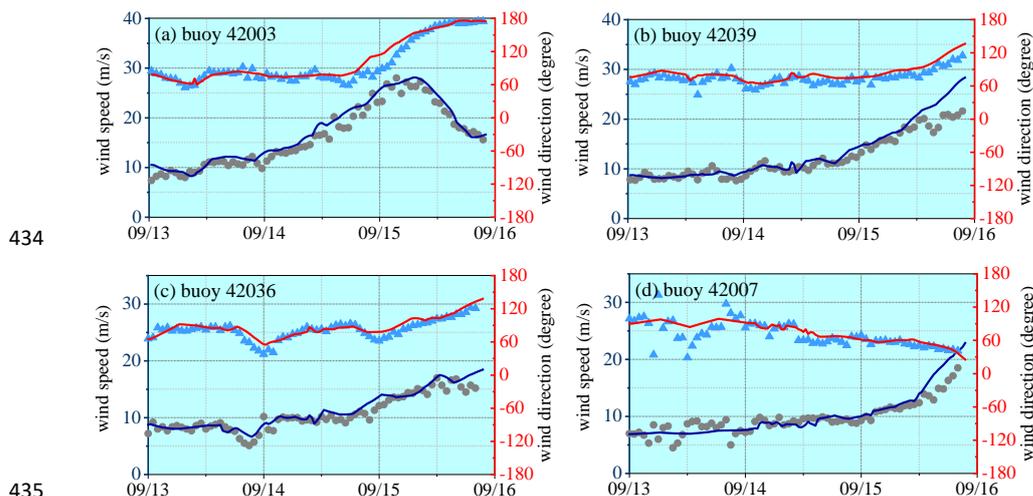

409 field. The H\*wind dataset integrates all field data available during a hurricane event and is  
410 usually considered to be highly accurate in a certain range affected by the relevant hurricane  
411 (Fan et al., 2009; Liu et al., 2017; Chen and Yu, 2017). The H\*wind data is issued every 3 h  
412 with a grid resolution of 6 km and a spatial extent of  $8^\circ \times 8^\circ$  around the hurricane center.  
413 Because the H\*wind data does not cover the entire simulation domain, the ECMWF data  
414 must be supplemented. The ECMWF data has a spatial resolution of  $0.125^\circ$  and temporal  
415 resolution of 6 h, which is good enough to represent the background wind field. The wind  
416 data from different sources is combined by setting a transition zone so that

$$417 \quad \mathbf{U}_{10} = \begin{cases} \mathbf{U}_H & (r < R_{\max}) \\ \frac{R_{\max} - r}{0.3R_{\max}} \mathbf{U}_H + \frac{r - 0.7R_{\max}}{0.3R_{\max}} \mathbf{U}_E & (0.7R_{\max} < r < R_{\max}) \\ \mathbf{U}_E & (r > R_{\max}) \end{cases} \quad (13)$$

418 where,  $\mathbf{U}_H$  and  $\mathbf{U}_E$  denote the wind velocity vectors from the H\*wind dataset and the  
419 ECMWF dataset, respectively;  $r$  is the distance from the hurricane center;  $R_{\max}$  is the  
420 maximal distance of the H\*wind boundary to the hurricane center. The time interval of the  
421 wind field is interpolated to 0.5 h to satisfy the computational condition. The normalized  
422 interpolation method of Fan et al. (2009), which ensures the greatest likelihood that the  
423 structure of hurricane wind field is not affected by the interpolation, is applied for this  
424 purpose. The wind field constructed in such a manner agrees well with the buoy data as  
425 shown in Figures 8 and 9. To include the effect of ocean currents (Fan et al., 2009), the  
426 global reanalysis database generated with HYCOM (HYbrid Coordinate Ocean Model) and  
427 NCODA (Navy Coupled Ocean Data Assimilation) is also utilized as the model input. The  
428 data has a spatial resolution of  $1/12^\circ$  and a temporal resolution of 3 h. The topography data  
429 is from the ETOPO1 datasets and has a spatial resolution of  $1'$ .

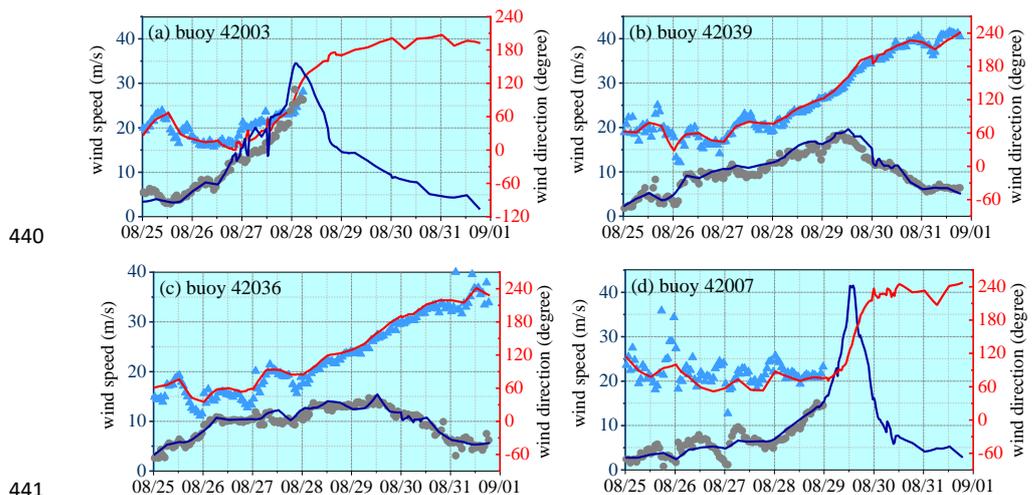

430 Buoy data published by NDBC (National Data Buoy Center, National Oceanic and  
431 Atmospheric Administration) are used to validate the model results on representative wave  
432 parameters including  $H_s$ ,  $T_{02}$  and spectral wave parameters in both deep- and shallow waters.  
433 The locations of buoys are shown in Figure 10.

434

435

436 Figure 8. Comparison of reconstructed time series of wind velocity with observed data at  
437 locations of the NDBC buoys during Hurricane Ivan. Scattered dots and triangles are buoy  
438 data of wind speed and wind direction, respectively. Blue and red lines are constructed wind  
439 speed and wind direction, respectively.

440

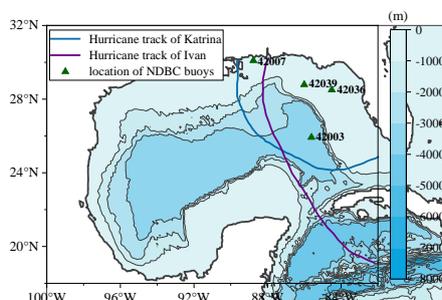

441

442 Figure 9. Comparison of reconstructed time series of wind velocity with observed data at  
443 locations of the NDBC buoys during Hurricane Katrina. Scattered dots and triangles are  
444 buoy data of wind speed and wind direction, respectively. Blue and red lines are constructed  
445 wind speed and wind direction, respectively. At buoy 42003 and 42007, there is data  
446 missing.

#### 447 4.2 Model setup

448 The computational domain, as shown in Figure 10, covers the area affected by both  
449 Hurricane Ivan (2004) and Hurricane Katrina (2005), ranging from 100°W to 82°W and  
450 from 18°N to 32°N within Gulf of Mexico. Considering a minimal time period for model  
451 warm-up, simulation of Hurricane Ivan is initialized at 00:00 UTC, 12 September 2004 and  
452 continues for nearly 4 days until 21:00 UTC, 15 September 2004. Simulation of Hurricane  
453 Katrina is initialized at 00:00 UTC, 25 August 2005 and continues for nearly 7 days until  
454 18:00 UTC, 31 August 2005. A time step of 10 min is fixed. We assume 36 directional  
455 intervals with a constant increment of 10° and 35 frequency intervals that increase  
456 logarithmically over the range of 0.0373-1.048 Hz. The numerical results obtained with the  
457 ST-XY source-term option are compared to those obtained with other options. The ST2,  
458 ST4, ST6 options are implemented with the default setting.

459

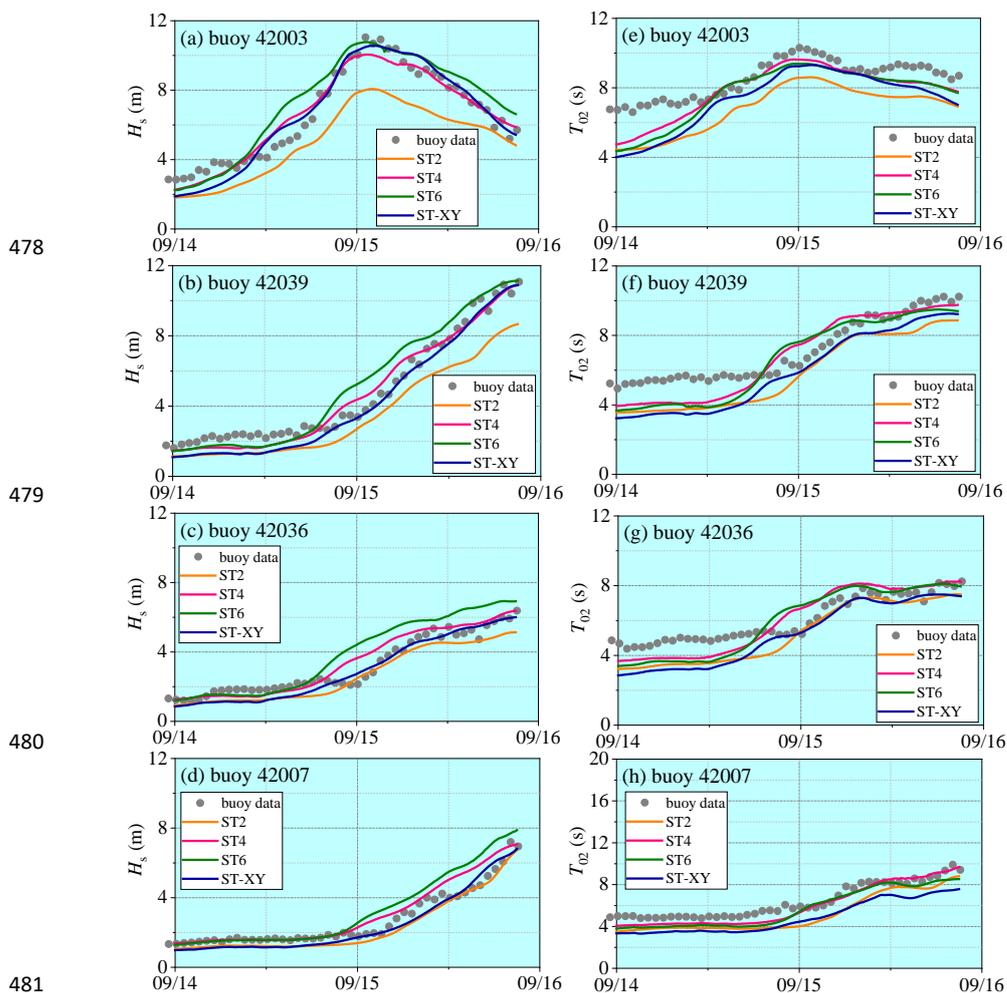

460 Figure 10. The computational domain. Tracks of hurricanes are shown with solid lines. The  
461 NDBC buoys are marked by triangles. Water depth at the locations of buoys 42003, 42039,  
462 42036 and 42007 are 3265 m, 281 m, 50.9 m and 14.9 m, respectively.

#### 463 4.3 Comparison of wave parameters

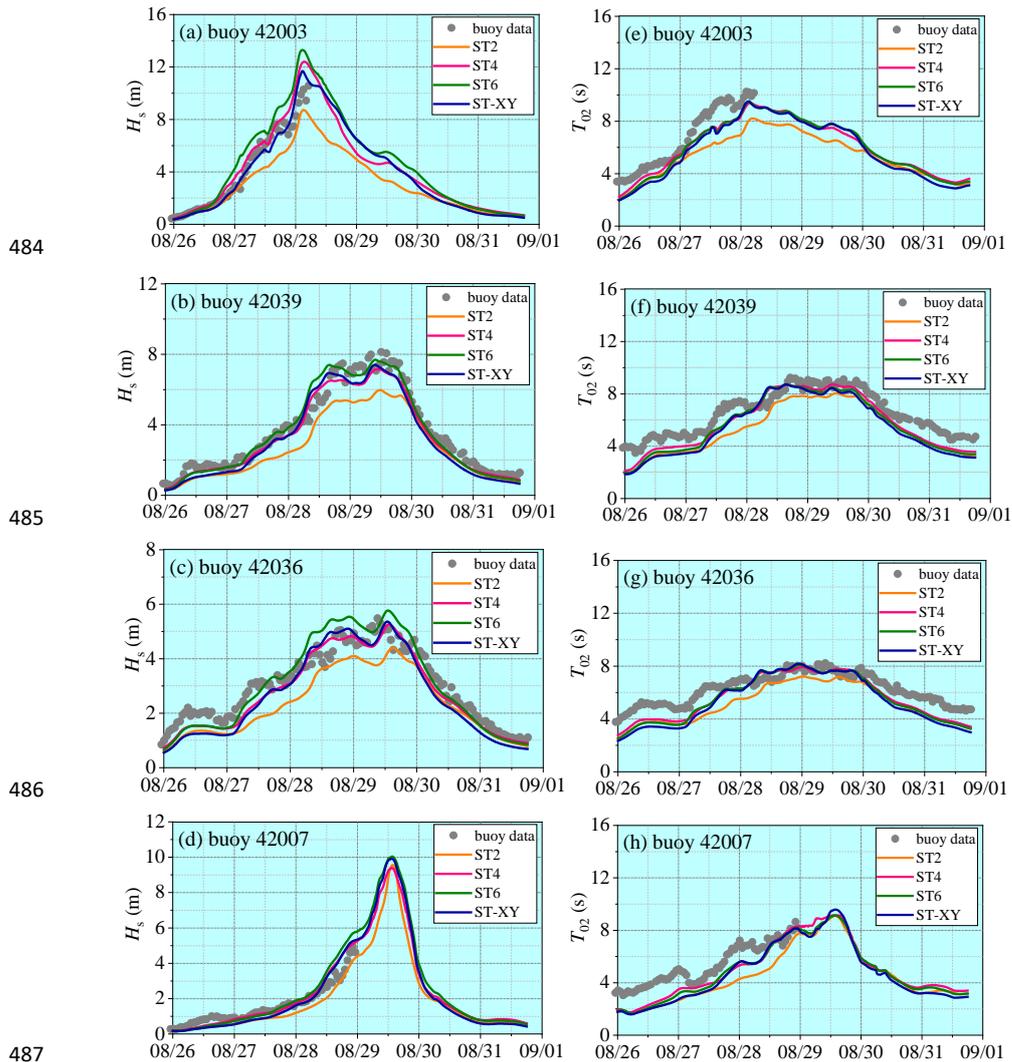

464 The model results on the time variations of the significant wave height  $H_s$  and the mean  
465 wave period  $T_{02}$  at the locations of the buoys during Hurricane Ivan and Hurricane Katrina  
466 are shown in Figures 11 and 12, respectively. The observed data are also plotted for  
467 comparison. It can be seen that the significant wave height  $H_s$  obtained with the ST-XY  
468 option agrees fairly well with the buoy data and performs better than the ST2 and ST6  
469 options. The peak value and peak time of the significant wave height are accurately

470 represented. In comparison, the significant wave height  $H_s$  is obviously overestimated by the  
471 ST6 option but underestimated by the ST2 option. The ST4 option performs also very well,  
472 but still show some underestimation of the peak values of  $H_s$  (as shown in Figures 11a and  
473 12a) and some overestimation of  $H_s$  before it reaches its maximum value (as shown in  
474 Figures 11b-d). The numerical results for the mean wave period  $T_{02}$  are shown to be  
475 generally less accurate than those for the significant wave height  $H_s$ , especially during the  
476 period before and after the hurricane event. An underestimation is evident. But, the peak  
477 values of  $T_{02}$  are still reasonably simulated.

481  
482 Figure 11. Comparisons of the computed variations (lines) of (a) – (d)  $H_s$  and (e) – (h)  $T_{02}$   
483 with buoy data (dots) during Hurricane Ivan.

484  
 485  
 486  
 487  
 488 Figure 12. Comparisons of the computed variations (lines) of (a) – (d)  $H_s$  and (e) – (h)  $T_{02}$   
 489 with buoy data (dots) during Hurricane Katrina.

490 **4.4 Comparison of wave spectra**

491 For the detailed description of a wave spectrum, the peak value  $E_p$ , the peak  
 492 frequency  $f_p$  of the spectrum as well as its mean square slope  $M_s$  are defined to describe  
 493 the frequency spectrum; the dominant wave propagation direction  $\theta_m$ , the mean wave  
 494 propagation direction  $\bar{\theta}$  and the directional spreading width  $\Delta\theta$  are defined to describe  
 495 the directional spectrum. In particular,

496 
$$E_p = \max \left( \int_0^{2\pi} E(f, \theta) d\theta \right) \quad (14)$$

497 
$$M_s = \iint k^2 E(f, \theta) df d\theta \quad (15)$$

498 
$$E(\theta_m) = \max \left( \int E(f, \theta) df \right) \quad (16)$$

499 
$$E(\theta_e) \geq 0.1 \max \left( \int E(f, \theta) df \right) \quad (17)$$

500 
$$\bar{\theta} = \frac{1}{2} (\theta_{e1} + \theta_{e2}) \quad (18)$$

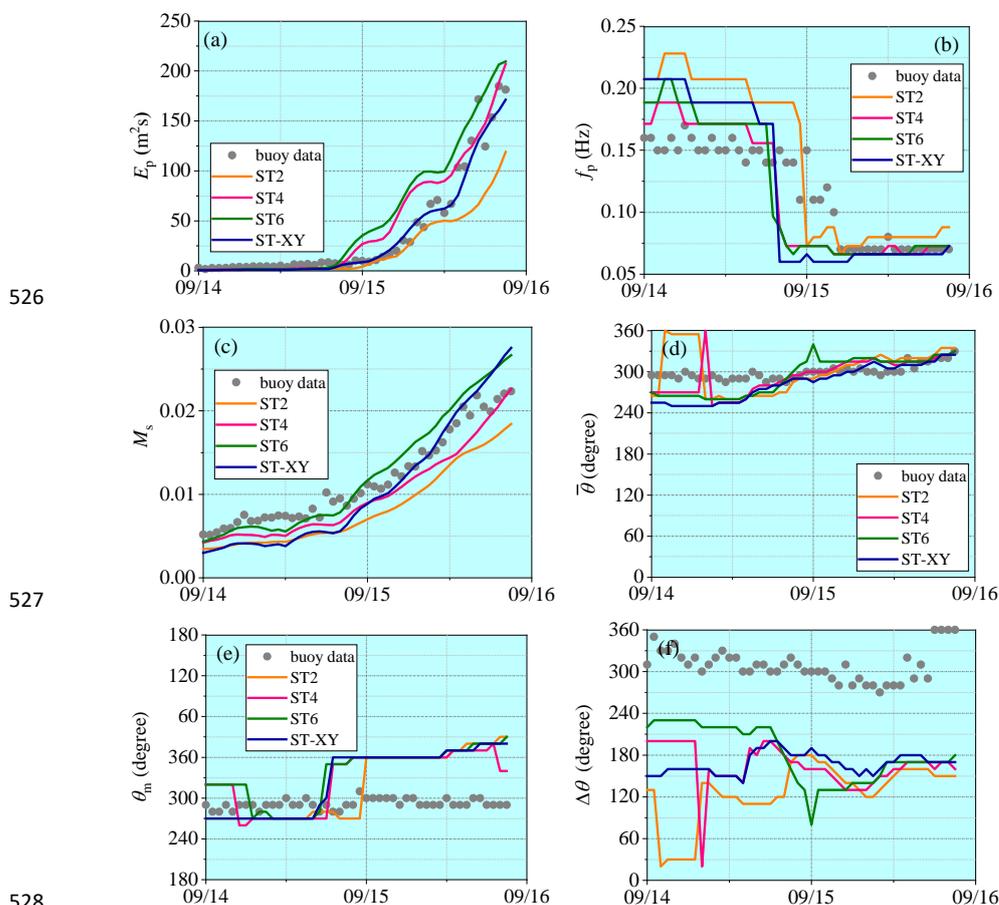

501 
$$\Delta\theta = \theta_{e2} - \theta_{e1} \quad (19)$$

502 where,  $E_p$  is the peak value of the frequency spectrum,  $f_p$  is the corresponding peak  
503 frequency;  $M_s$  is the mean square slope of frequency spectrum, representing the effect of  
504 high-frequency wave components;  $E(\theta_m)$  is the peak of the directional spectrum and  $\theta_m$   
505 is the corresponding direction, called the main wave direction;  $\theta_e$  is called the efficient  
506 wave direction beyond which the wave energy is below 10% of the peak value of the  
507 directional spectrum;  $\theta_{e1}$  and  $\theta_{e2}$  are the lower and higher limits of  $\theta_e$ ;  $\bar{\theta}$  is the mean  
508 wave propagation direction while  $\Delta\theta$  is the directional range of the effective wave  
509 propagation.

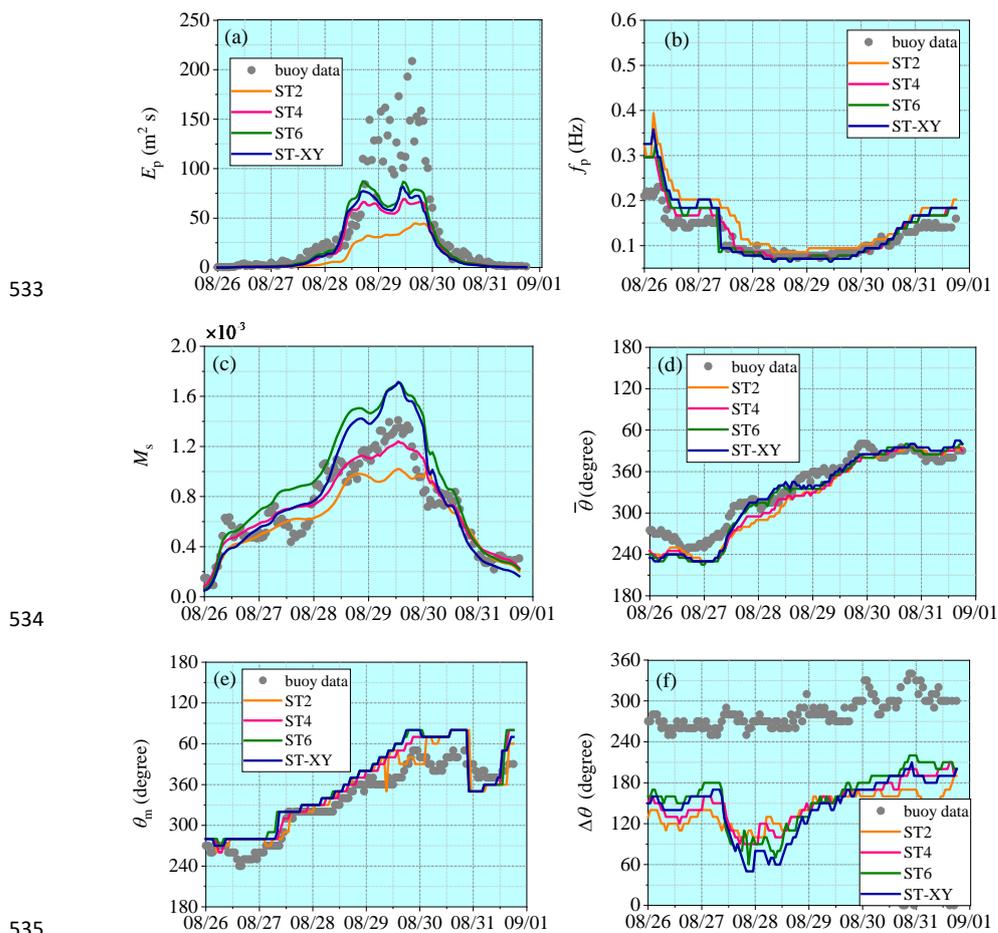

510 Comparison of the computed wave spectra with observations is made at the locations of  
511 buoys 42039 and 42036, where a relatively complete data series have been recorded during  
512 both hurricane events. Variations of the spectral wave parameters in the deep-water  
513 condition (at buoy 42039) are presented in Figures 13 and 14 while those in the shallow  
514 water condition (at buoy 42036) are presented in Figures 15 and 16. Accuracy of the  
515 numerical results for the peak spectrum value  $E_p$  is quite similar to that for the  
516 representative wave parameters such as  $H_s$ . The result obtained with the ST-XY option can  
517 catch the extreme wave energy condition very well, while the ST6 option always  
518 overestimate and the ST2 option underestimate it. The result obtained with the ST4 option  
519 overestimates  $E_p$  under the moderate wind conditions before the extreme events. The  
520 numerical results for the peak frequency  $f_p$  agrees with observations well during both

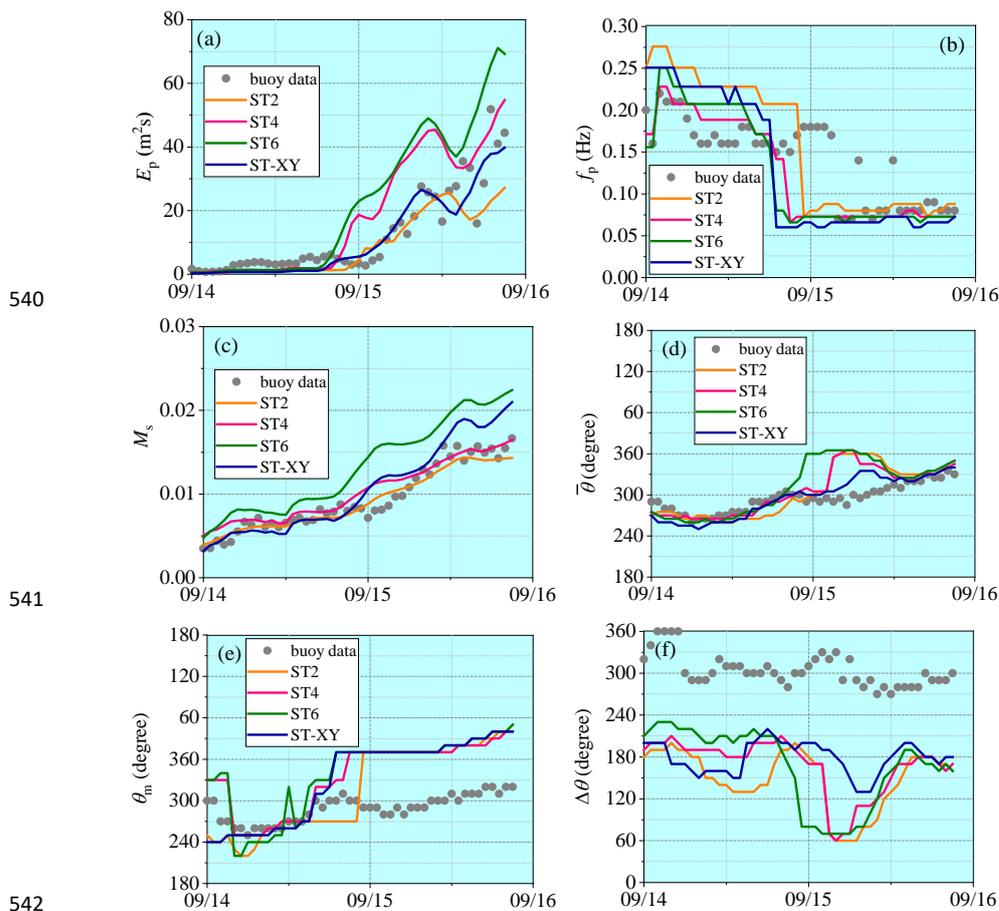

521 hurricane events.  $M_s$  is also satisfactorily simulated, which means that the high frequency  
 522 part of the wave spectrum is well described by the numerical model. It may be necessary to  
 523 point out that, different from the results for the representative wave parameters, the peak of  
 524  $E_p$  may not be correctly represented by any package of the source terms under our  
 525 consideration in some cases, as shown in Figure 14a.

529 Figure 13. Comparisons of wave spectral parameters with observations at buoy 42039  
 530 during Hurricane Ivan. (a) spectrum peak value; (b) peak frequency; (c) mean square slope;  
 531 (d) mean wave propagation direction; (e) main wave propagation direction; (f) wave  
 532 propagation spread width.

536 Figure 14. Comparisons of wave spectral parameters with observations at buoy 42039  
537 during Hurricane Katrina. (a) spectrum peak value; (b) peak frequency; (c) mean square  
538 slope; (d) mean wave propagation direction; (e) main wave propagation direction; (f) wave  
539 propagation spread width.

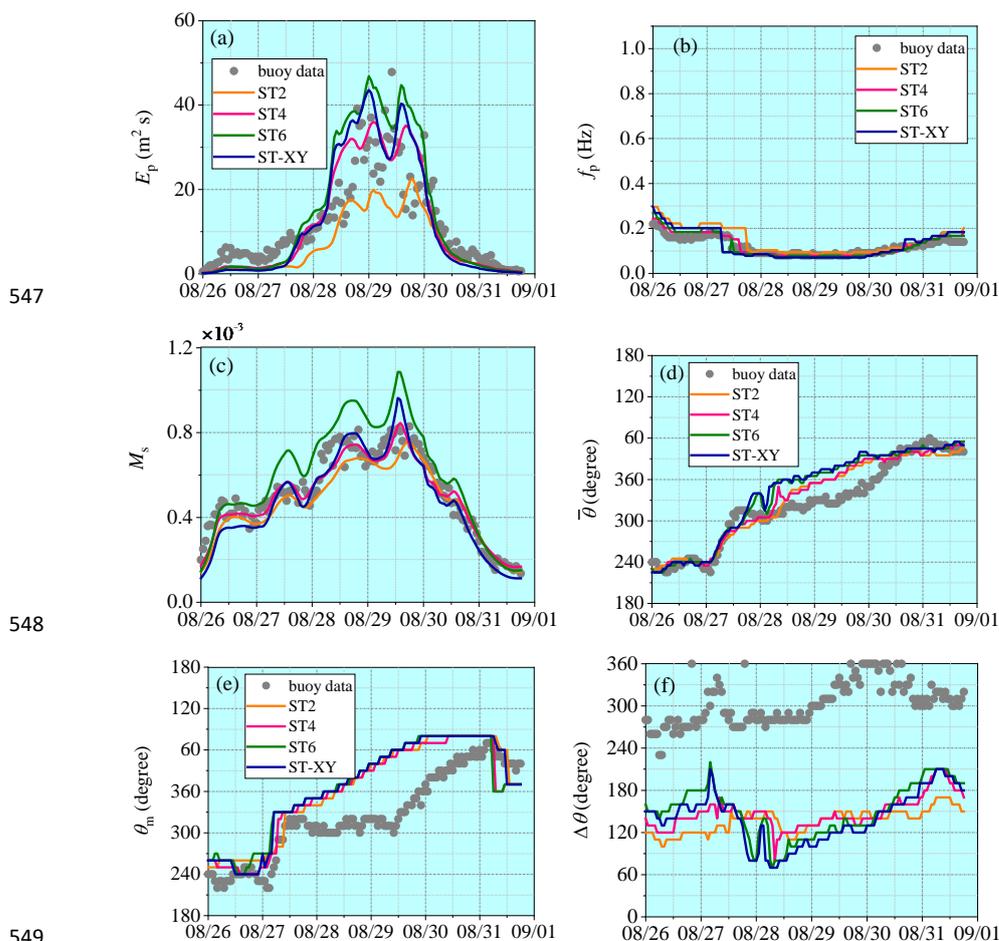

540

541

542

543 Figure 15. Comparisons of wave spectral parameters with observations at buoy 42036  
544 during Hurricane Ivan. (a) spectrum peak value; (b) peak frequency; (c) mean square slope;  
545 (d) mean wave propagation direction; (e) main wave propagation direction; (f) wave  
546 propagation spread width.

550 Figure 16. Comparisons of wave spectral parameters with observations at buoy 42036  
 551 during Hurricane Katrina. (a) spectrum peak value; (b) peak frequency; (c) mean square  
 552 slope; (d) mean wave propagation direction; (e) main wave propagation direction; (f) wave  
 553 propagation spread width.

554 It is also demonstrated that the numerical results for the main wave propagation  
 555 direction and the mean wave propagation direction obtained with the ST-XY option and  
 556 other source-term options are all equally good. However, the numerical result for the  
 557 directional range of the effective wave propagation is obvious narrower than observed one.  
 558 This, however, may not be an error of the numerical model since the directional range of the  
 559 effective wave propagation depends significantly on the methods employed (Earle et al.,

560 1999; Kim et al., 1995). In this study, Longuet-Higgins' method (Longuet-Higgins et al.,  
561 1963) is used to build the directional wave spectrum from observed data. This method  
562 always leads a broader directional spectrum than other methods with the same parameters  
563 (Earle et al. (1999)'s Figure 2).

## 564 **5. Conclusion**

565 This study is aimed to evaluate the performance of the improved formulas for the wind  
566 energy input and the wave energy dissipation, i.e., the ST-XY source-term option. The  
567 numerical results are obtained with the coupled AWBLM-WWIII model. Both  
568 duration-limited waves under idealized conditions and hurricane-generated waves, in both  
569 deep and shallow waters are studied. The standard source-term packages of ST2, ST4 and  
570 ST6 embedded in WWIII are chosen for comparison. Detailed comparisons are made for not  
571 only the representative wave parameters, including the significant wave height, the mean  
572 wavelength and the mean wave period, but also the characteristic parameters for the  
573 frequency spectrum and the directional spreading function. The effect of breaking on ocean  
574 wave modeling is fully discussed.

575 The numerical results show that the ST-XY source-term package performs better than  
576 other standard options in general. At the early wave-development stage, the ST-XY option  
577 leads to a better agreement of the computed wave energy with the empirical results while  
578 other source-term options all tend to underestimate the wave energy. At the equilibrium  
579 stage, the results obtained with the ST-XY option approaches the Pierson-Moskowitz limit  
580 while ST2 option significantly underestimates the wave energy. The ST-XY option is also  
581 effective for ocean wave modeling under both deep- and shallow- water conditions and  
582 gives results in good agreement with field data. For hurricane-generated waves, model  
583 results obtained with the ST-XY option agrees well with the buoy data and are obviously  
584 better than those obtained with other source-term options. On the other hand, the ST6 option  
585 often overestimates wave energy while ST2 option leads to an obvious underestimation. The  
586 ST4 option performs fairly well but still show some underestimation of the peak value of  
587 significant wave height and some overestimation of the significant wave height before its

588 peak value is achieved.

589 Wave breaking significantly affect ocean wave modeling, especially at younger wave  
590 ages and in shallower waters. At the early wave-development stage, a significant part of the  
591 peak wind energy input takes place under breaking condition, and the proportion decreases  
592 gradually as the wave development continues. In shallow waters, the peak value of wind  
593 energy input taking place under breaking conditions are always higher than that under  
594 non-breaking conditions throughout the early wave-development stage to the equilibrium  
595 stage.

596 In summary, the improved formula of Xu and Yu (2020), which includes both breaking  
597 effect and the effect of air-flow separation on the leesides of steep wave crests in a  
598 consistent way, has a satisfactory performance within the coupled AWBLM-WWIII model.  
599 It is physics-based and is verified to be effective for ocean wave modeling under both  
600 moderate and extreme wind conditions, at all wave-development stages, and in deep to  
601 shallow waters, thus has a broad applicability.

## 602 **Competing interests**

603 The authors declare that there is no conflict of interest.

## 604 **Authors' contributions**

605 Y. Xu and X. Yu conceived of the presented idea. Y. Xu performed the computations. X.  
606 Yu supervised the project. Both authors discussed the results and contributed to the final  
607 manuscript.

## 608 **Funding**

609 This research is supported by National Natural Science Foundation of China (NSFC)  
610 under grant No. 11732008.
