## Abstract.

Modelling magma transport requires robust numerical schemes for chemical advection. Current numerical schemes vary in their ability to be mass conservative, computationally efficient, and accurate. This study compares four of the most commonly used numerical schemes for advection: an upwind scheme, a weighted essentially non-oscillatory (WENO-5) scheme, a semi-Lagrangian (SL) scheme, and a marker-in-cell (MIC) method. ~~We assess the~~ The behaviour of these schemes is assessed using the passive advection of two different magmatic compositions. This is coupled in 2D with the temporal evolution of a melt anomaly that generates porosity waves. All algorithms, except the upwind scheme, are able to predict the melt composition with reasonable accuracy. In terms of total running time and when multithreaded, ~~the upwind and SL schemes are the fastest,~~ SL and WENO-5 schemes show similar performance, while the MIC scheme is the slowest. The WENO-5 scheme ~~shows intermediate total running time but~~ exhibits reasonable total run time, has the lowest amount of mass loss ~~and therefore is,~~ and is therefore best suited for this problem.

## 1 Introduction

Mechanisms of magma ascent and emplacement within the lithosphere and upper asthenosphere remain largely unconstrained (e.g., Connolly and Podladchikov, 2007b; Katz et al., 2022). Studies have attempted to address this problem using techniques ranging from geophysical measurements of the present-day lithosphere to geochemical analysis of the rock record. However, geophysical studies are hampered by indirect measurements, and natural samples in geochemical studies represent only the end-product of the melting processes (Brown, 2013; Clemens et al., 2022; Johnson et al., 2021). Comparatively, numerical modelling allows investigation of these processes at a range of scales in space and time (e.g., Keller, 2013; Katz and Weatherley, 2012).

To numerically model such open systems, it is necessary to be able to describe the chemical and physical processes responsible for magma ascent in a rock. At low melt fractions and in the absence of externally applied stress, the physical processes are based on the continuum formulation of two-phase flow. It takes into account the concurrent mechanisms of rock matrix compaction and buoyancy of partial melt in an interconnected porous network (e.g., Scott and Stevenson, 1984; McKenzie, 1984). This formulation is based on mass and momentum conservation, and an appropriate set of constitutive relationships. In addition, conservation of energy needs to be ensured to link mechanical to chemical processes (e.g., Katz, 2008). Chemical processes, such as phase reactions, can be considered using thermodynamics and/or kinetics and relate the equilibration of the

melt with the hosting rock (e.g., Omlin et al., 2017; Bessat et al., 2022). They contribute to the transport dynamics by changing rock properties, such as density, viscosity, porosity and permeability (Jha et al., 1994; Aharonov et al., 1995b; Keller and Katz, 2016). However, the amount of melt interacting with the rock is also modulated by transport mechanisms (Kelemen et al., 1997; Spiegelman and Kenyon, 1992; Aharonov et al., 1995a). Therefore, the development of integrated models that successfully describe the complex interaction between reaction and transport is key to understanding melting and melt extraction at all scales.

Numerous numerical studies have investigated reactive melt transport. It has been shown that melts that partially crystallise or dissolve the host rock could be a viable mechanism for channelling flow and creating heterogeneities in the mantle, in the context of oceanic middle ridges (Aharonov et al., 1997; Spiegelman et al., 2001) and sub-arc mantle (Bouilhol et al., 2011). Concerning lower crust melting, this approach has mainly been used to understand the processes of chemical differentiation and the compositional range of magma in mafic systems (e.g., Jackson et al., 2005; Solano et al., 2012; Riel et al., 2019).

One challenge of reactive melt transport modelling is the advection of the melt composition through its ascent. This part, which is mathematically ~~trivial as it is well understood, being~~ described by a ~~simple~~ mass balance equation, is numerically challenging (e.g., LeVeque, 1992). This is mainly due to the fact that most numerical models are based on an Eulerian frame of reference, where the discretised space is fixed in space and in time. In contrast, transport is by essence better defined from a Lagrangian perspective, where the observer follows the particles of fluid as they move. In addition, two-phase flow models are at least 2D problems due to the formation of channels (e.g., Barcilon and Lovera, 1989; Connolly and Podladchikov, 2007b) and to the fact that mass cannot be transported efficiently in 1D in the melt (Jordan et al., 2018). This brings limitation to the resolution of the models and hence requires accurate advection schemes.

This study compares four numerical schemes applied to the problem of the advection of magmatic composition: an upwind scheme, a weighted essentially non-oscillatory (WENO) scheme, a semi-Lagrangian (SL) scheme and a marker-in-cell (MIC) method. This selection provides a ~~good~~ representation of the different approaches to solving advection problems that are commonly used in a wide range of applications. We assess the performance of each scheme in terms of accuracy, mass conservation and computational time. A 2D model ~~that couples coupling~~ chemical advection with a two-phase flow solver is then used to evaluate which algorithm is best suited to this problem.

## 2 Governing equations

Chemical transport in two-phase flow systems is described by the four mass conservation equations of the system (e.g., Aharonov et al., 1997). The first two equations describe the conservation of the total mass of the solid and the liquid:

$$55 \quad \frac{\partial [(1 - \phi)\rho_s]}{\partial t} = -\nabla \cdot [(1 - \phi)\mathbf{v}_s\rho_s], \quad (1)$$

$$\frac{\partial (\phi\rho_f)}{\partial t} = -\nabla \cdot (\phi\mathbf{v}_f\rho_f), \quad (2)$$

where  $f$  and  $s$  ~~are represent~~ the fluid and solid phases,  $t$  is the time (in s),  $\phi$  is the fluid-filled porosity,  $\rho$ , the density of the respective phase ( $\text{kg}\cdot\text{s}^{-3}$ ),  $\mathbf{v}$ , the velocity of the respective phase ( $\text{m}\cdot\text{s}^{-1}$ ). The last two equations express the conservation of each chemical component within the solid and fluid phases:

$$60 \quad \frac{\partial [(1-\phi)\rho_s C_e^s]}{\partial t} = \nabla \cdot [D_e^s(1-\phi)\rho_s \nabla C_e^s - (1-\phi)\mathbf{v}_s \rho_s C_e^s], \quad (3)$$

$$\frac{\partial (\phi \rho_f C_e^f)}{\partial t} = \nabla \cdot (\mathbf{D}_e^f \phi \rho_f \nabla C_e^f - \phi \mathbf{v}_f \rho_f C_e^f), \quad (4)$$

where  $C_e$  is the mass fraction of the chemical component  $e$  in the respective phase,  $D_e^s$  is the solid diffusion coefficient of the chemical component  $e$  (in  $\text{m}^2\cdot\text{s}^{-1}$ ) and  $\mathbf{D}_e^f$ , the hydrodynamic dispersion tensor of the chemical component  $e$  in the fluid ( $\text{m}^2\cdot\text{s}^{-1}$ ). These four equations assume no mass transfer due to reactions between the solid and the liquid phases.

## 65 **2.1 Simplifications**

In this study, the advection of the chemical components transported by the liquid phase is considered and the diffusion term in Eqs. (3) and (4) is neglected. Since  $\rho_s$  is assumed to be constant and that the host rock has a fixed composition, Eq. (3) is omitted.

Subtracting Eq. (2) in Eq. (4), and dividing by  $\rho_f$  and  $\phi$  yields:

$$70 \quad \frac{\partial(C_e^f)}{\partial t} \frac{\partial C_e^f}{\partial t} = -\mathbf{v}_f \nabla \cdot (C_e^f). \quad (5)$$

Equation (5) is formally equivalent to Eq. (4) without the dispersion term. Moreover, Eq. (4) is written in conservative form, whereas Eq. (5) is expressed in Lagrangian or non-conservative form. ~~In addition, Eq. Equation~~ (5) removes the time dependence on  $\phi$  ~~and is linear. It is a common form used in the reactive transport modelling community (e.g., Carrera et al., 2022).~~

75 An expression for  $\mathbf{v}_f$  can be derived by coupling Eqs. (1) and (2) to the momentum conservation equations (e.g., McKenzie, 1984; Bercovici et al., 2001). These are usually solved before Eq. (5); a description of the system used in this study is provided below in section 5.1.

### **2.1.1 Numerical Methods**

## 3 Numerical Methods

80 Solving an advection equation using a linear Eulerian scheme leads to high numerical diffusion for first-order schemes, such as the upwind scheme (Courant et al., 1952), and to oscillations on sharp gradients for higher-order schemes (LeVeque, 2002).

The latter effect is described by Godunov's theorem (Godunov and Bohachevsky, 1959). This theorem states that linear Eulerian schemes of order of accuracy greater than one cannot preserve the monotonicity of the solution for sharp gradients, discontinuities or shocks. This has led to extensive developments in the design of high-order Eulerian non-linear schemes that can achieve high accuracy without bringing oscillations. Examples of such developments are the essentially non-oscillatory (ENO) methods (Harten et al., 1987), that later led to ~~weighted essentially non-oscillatory (WENO)~~ WENO schemes (Liu et al., 1994). These schemes are based on the idea of using a non-linear adaptive procedure to automatically choose the locally smoothest stencil and ~~earlier~~ early examples of applications include the modelling of shocks appearing in acoustics (e.g., Grasso and Pirozzoli, 2000) or solving the Hamilton-Jacobi equations (e.g., Jiang and Peng, 2000).

Another approach is to use schemes closer to Lagrangian perspective, such as the ~~Marker-In-Cell (MIC)~~ MIC (or alternatively named ~~Marker-And-Cell~~ marker-and-cell) method (e.g., Harlow et al., 1955; Gerya and Yuen, 2003a). It consists ~~at~~ of tracking individual particles on a Lagrangian frame and ~~to reinterpolate~~ reinterpolating them when needed on an Eulerian stationary ~~mesh~~ grid. This approach has the advantage of producing little numerical diffusion ~~and to be~~ being unconditionally stable and has been ~~used extensively to advect most fields in geodynamics, such as physical properties and compositions~~ extensively used in geodynamic models (e.g., Gerya, 2019; van Keken et al., 1997; Duret et al., 2011).

Finally, there are intermediate methods, such as semi-Lagrangian methods, trying to take advantages from both Eulerian and Lagrangian schemes (Robert, 1981; McDonald, 1984). These schemes look at different particles at each timestep, considering only particles whose final trajectories correspond to the position of ~~a fixed Eulerian grid~~ grid nodes. This has the advantage of only considering a number of particles equal to the resolution of the Eulerian grid and is computationally efficient. They are also unconditionally stable, but have issues with mass conservation (Chandrasekar, 2022). They were first developed for atmospheric modelling (e.g., Robert, 1981; Staniforth and Côté, 1991) and later successfully used in the plasma modelling community (e.g., Sonnendrücker et al., 1999).

To solve for Eq. (5) in the context of two-phase flow, we ~~implement and test~~ implemented and tested four different advection schemes that are representative of the approaches described above: an upwind scheme, a WENO scheme, a SL scheme and a MIC method.

### 3.1 Upwind scheme

The upwind scheme is among the simplest algorithm for solving an advection equation on an Eulerian grid (e.g., LeVeque, 1992). It is explicit and first-order in space and in time. It consists of using a spatially biased stencil that depends on the direction of the flow (Fig. 1).

#### 3.1.1 Spatial ~~discretization~~ discretisation

Using a first-order biased ~~spacial~~ spatial stencil, Eq. (5) can be approximated for ~~1~~ one chemical element and in 1D as:

**Figure 1.** Spatial stencil of the Upwind-upwind scheme in 1D. The blue box is the valid stencil for positive velocities and the yellow box for negative velocities.

$$\frac{\partial C_i}{\partial t} + v_{f,i} \frac{C_i^n - C_{i-1}^n}{\Delta x} = 0 \quad \text{for } v_{f,i} > 0,$$

$$\frac{\partial C_i}{\partial t} + v_{f,i} \frac{C_{i+1}^n - C_i^n}{\Delta x} = 0 \quad \text{for } v_{f,i} < 0,$$

$$115 \quad \frac{\partial C_i}{\partial t} + v_{f,i} \frac{C_i^n - C_{i-1}^n}{\Delta x} = 0 \quad \text{for } v_{f,i} > 0, \tag{6}$$

$$\frac{\partial C_i}{\partial t} + v_{f,i} \frac{C_{i+1}^n - C_i^n}{\Delta x} = 0 \quad \text{for } v_{f,i} < 0,$$

where  $i$  is a spatial index in the  $x$  direction and  $\Delta x$  is a constant increment in space the constant grid spacing and  $v_{f,i}$ , the  $x$  component of the fluid velocity.

### 3.1.2 Temporal discretizationdiscretisation

120 Combined with the first-order forward Euler method, we retrieve the classical upwind scheme from Eq. (6):

$$\frac{C_i^{n+1} - C_i^n}{\Delta t} + v_{f,i} \frac{C_i^n - C_{i-1}^n}{\Delta x} = 0 \quad \text{for } v_{f,i} > 0,$$

$$\frac{C_i^{n+1} - C_i^n}{\Delta t} + v_{f,i} \frac{C_{i+1}^n - C_i^n}{\Delta x} = 0 \quad \text{for } v_{f,i} < 0,$$

$$\frac{C_i^{n+1} - C_i^n}{\Delta t} + v_{f,i} \frac{C_i^n - C_{i-1}^n}{\Delta x} = 0 \quad \text{for } v_{f,i} > 0, \tag{7}$$

$$125 \quad \frac{C_i^{n+1} - C_i^n}{\Delta t} + v_{f,i} \frac{C_{i+1}^n - C_i^n}{\Delta x} = 0 \quad \text{for } v_{f,i} < 0,$$

where  $\Delta t$  is the timestep.

It can also be rewritten in a more compact form:

$$C_i^{n+1} = C_i^n - \Delta t \left[ v_{f,i}^+ \left( \frac{C_i^n - C_{i-1}^n}{\Delta x} \right) + v_{f,i}^- \left( \frac{C_{i+1}^n - C_i^n}{\Delta x} \right) \right], \quad (8)$$

where

130  $v_{f,i}^+ = \max(v_{f,i}, 0),$

$v_{f,i}^- = \min(v_{f,i}, 0).$

$v_{f,i}^+ = \max(v_{f,i}, 0),$

$v_{f,i}^- = \min(v_{f,i}, 0).$

135 This scheme is well known to produce a lot of numerical diffusion and is bounded by the following Courant–Friedrichs–Lewy (CFL) condition, for  $p$  dimensions:

$$\Delta t \left( \sum_{j=1}^p \frac{|v_{f_j}|}{\Delta x_j} \right) \leq C_{\max} = 1,$$

where  $C_{\max}$  is the maximum Courant (C<sub>o</sub>) number (e.g., Hirsch, 2007). In addition, it is not mass conservative for non-constant  $v_f$ , especially for divergent flow.

140 **3.2 Weighted essentially non-oscillatory scheme**

Weighted ~~Essentially Non-Oscillatory schemes (WENO)~~ essentially non-oscillatory schemes were developed by Liu et al. (1994). The reader can refer to Shu (2009) for a comprehensive review of the development of WENO schemes and Pawar and San (2019) for implementations using Julia.

145 They are high order schemes able to resolve sharp gradient, produce little numerical diffusion but also follow the same CFL condition as the Upwind-upwind scheme. The key idea behind them ~~is~~ is to use a non-linear adaptive procedure to automatically choose the locally smoothest stencil. This ~~allow~~ allows WENO schemes to dispose of oscillations when advecting sharp gradients.

We use a 5th order in space finite-difference approach for non-conservative problemproblems, referenced as WENO-5 hereafter.

150 **3.2.1 Spatial ~~Discretization~~discretisation**

Equation (5) can be ~~discretized~~discretised in space using the WENO-5 scheme similarly to the upwind scheme, in 1D~~and for~~  
~~1 element~~, for one chemical element and for a single grid point such as:

$$\frac{\partial C_i}{\partial t} + v_{f,i}^+ \left( \frac{C_{i+\frac{1}{2}}^L - C_{i-\frac{1}{2}}^L}{\Delta x} \right) + v_{f,i}^- \left( \frac{C_{i+\frac{1}{2}}^R - C_{i-\frac{1}{2}}^R}{\Delta x} \right) = 0, \quad (9)$$

where

155 
$$\begin{aligned} C_{i+\frac{1}{2}}^L = & \underbrace{w_0^L \left( \frac{1}{3}C_{i-2} - \frac{7}{6}C_{i-1} + \frac{11}{6}C_i \right) +} \\ & \underbrace{w_1^L \left( -\frac{1}{6}C_{i-1} + \frac{5}{6}C_i + \frac{1}{3}C_{i+1} \right) +} \\ & \underbrace{w_2^L \left( \frac{1}{3}C_i + \frac{5}{6}C_{i+1} - \frac{1}{6}C_{i+2} \right)}, \end{aligned}$$

160 
$$\begin{aligned} C_{i-\frac{1}{2}}^R = & \underbrace{w_0^R \left( -\frac{1}{6}C_{i-2} + \frac{5}{6}C_{i-1} + \frac{1}{3}C_i \right) +} \\ & \underbrace{w_1^R \left( \frac{1}{3}C_{i-1} + \frac{5}{6}C_i - \frac{1}{6}C_{i+1} \right) +} \\ & \underbrace{w_2^R \left( \frac{11}{6}C_i - \frac{7}{6}C_{i+1} + \frac{1}{3}C_{i+2} \right)}. \end{aligned}$$

$$\begin{aligned} C_{i+\frac{1}{2}}^L = & \underbrace{w_0^L \left( \frac{1}{3}C_{i-2} - \frac{7}{6}C_{i-1} + \frac{11}{6}C_i \right) +} \\ & \underbrace{w_1^L \left( -\frac{1}{6}C_{i-1} + \frac{5}{6}C_i + \frac{1}{3}C_{i+1} \right) +} \\ & \underbrace{w_2^L \left( \frac{1}{3}C_i + \frac{5}{6}C_{i+1} - \frac{1}{6}C_{i+2} \right)}, \end{aligned}$$

165 
$$\begin{aligned} C_{i-\frac{1}{2}}^R = & \underbrace{w_0^R \left( -\frac{1}{6}C_{i-2} + \frac{5}{6}C_{i-1} + \frac{1}{3}C_i \right) +} \\ & \underbrace{w_1^R \left( \frac{1}{3}C_{i-1} + \frac{5}{6}C_i - \frac{1}{6}C_{i+1} \right) +} \\ & \underbrace{w_2^R \left( \frac{11}{6}C_i - \frac{7}{6}C_{i+1} + \frac{1}{3}C_{i+2} \right)}. \end{aligned}$$

**Table 1.** Optimal weights for WENO-5 scheme

$d_k$	$k=0$	$k=1$	$k=2$
$d_k^L$	0.1	0.6	0.3
$d_k^R$	0.3	0.6	0.1

Here,  $C_{i-\frac{1}{2}}^L$  and  $C_{i+\frac{1}{2}}^R$  are omitted to avoid redundancy. They can be obtained by shifting the index by -1 and 1 respectively.

~~Non-linear~~ The non-linear weights  $w$  are defined as:

$$170 \quad w_k^L = \frac{\alpha_k}{\alpha_0 + \alpha_1 + \alpha_2}, \quad \alpha_k = \frac{d_k^L}{(\beta_k + \epsilon)^2}, \quad k = 0, 1, 2$$

$$w_k^R = \frac{\alpha_k}{\alpha_0 + \alpha_1 + \alpha_2}, \quad \alpha_k = \frac{d_k^R}{(\beta_k + \epsilon)^2}, \quad k = 0, 1, 2$$

$$w_k^L = \frac{\alpha_k}{\alpha_0 + \alpha_1 + \alpha_2}, \quad \alpha_k = \frac{d_k^L}{(\beta_k + \epsilon)^2}, \quad k = 0, 1, 2,$$

$$w_k^R = \frac{\alpha_k}{\alpha_0 + \alpha_1 + \alpha_2}, \quad \alpha_k = \frac{d_k^R}{(\beta_k + \epsilon)^2}, \quad k = 0, 1, 2.$$

175 The values of the optimal weights  $d_k^L$  and  $d_k^R$  are given in Table 1 and  $\epsilon$  is fixed at  $1 \times 10^{-6}$  represents the machine epsilon, the relative approximation error due to rounding in floating point arithmetic, and is used to avoid division by zero.

Smoothness indicators  $\beta$  are equal to:

$$\beta_0 = \frac{13}{12} (C_{i-2} - 2C_{i-1} + C_i)^2 + \frac{1}{4} (C_{i-2} - 4C_{i-1} + 3C_i)^2,$$

$$\beta_1 = \frac{13}{12} (C_{i-1} - 2C_i + C_{i+1})^2 + \frac{1}{4} (C_{i-1} - C_{i+1})^2,$$

$$180 \quad \beta_2 = \frac{13}{12} (C_i - 2C_{i+1} + C_{i+2})^2 + \frac{1}{4} (3C_i - 4C_{i+1} + 3C_{i+2})^2.$$

$$\beta_0 = \frac{13}{12} (C_{i-2} - 2C_{i-1} + C_i)^2 + \frac{1}{4} (C_{i-2} - 4C_{i-1} + 3C_i)^2,$$

$$\beta_1 = \frac{13}{12} (C_{i-1} - 2C_i + C_{i+1})^2 + \frac{1}{4} (C_{i-1} - C_{i+1})^2,$$

$$\beta_2 = \frac{13}{12} (C_i - 2C_{i+1} + C_{i+2})^2 + \frac{1}{4} (3C_i - 4C_{i+1} + 3C_{i+2})^2.$$

**Figure 2.** Spatial stencil of the WENO-5 scheme in 1D.  $C^L$  is used for positive velocities and  $C^R$  for negative velocities. The blue boxes are valid stencils for positive velocities and the yellow and orange boxes are valid for negative velocities.

185 The WENO-5 scheme requires, in 1D ~~requires~~, a stencil of 5-five points biased towards the left for positive velocities and  
5-five points biased towards the right for negative velocities as shown on Fig. 2. ~~Careful consideration must then be given~~  
~~to boundary conditions for complex problems.~~ This commonly requires two ghost points on each side of the model to apply  
the boundary conditions. To extend this scheme to 2D, two new terms can be added to 9 for the new positive and negative  
component of  $v_f$ . The expressions of  $C$  at half points of the new index can be derived using the same formulae as in 1D for the  
190 new direction.

### 3.2.2 Temporal ~~discretization~~ discretisation

~~WENO-Weighted essentially non-oscillatory~~ schemes are not stable using the standard forward Euler time integration method  
(Wang and Spiteri, 2007). The most commonly used discretisation is the third-order Strong Stability Preserving (SSP) explicit  
Runge-Kutta method (e.g., Jiang and Shu, 1996; Ghosh and Baeder, 2012). SSP-Strong Stability Preserving schemes are used  
195 to fully capture discontinuous solutions and are therefore ~~very useful~~ well-suited for solving hyperbolic partial differential  
equations (Gottlieb et al., 2001).

The third-order SSP Runge-Kutta for Eq. (5) for 1-one chemical element can be written as:

$$C_i^1 = C_i^m - \Delta t L(C_i^m),$$

$$C_i^2 = \frac{3}{4}C_i^m + \frac{1}{4}[C_i^1 - \Delta t L(C_i^1)],$$

$$200 \quad C_i^{n+1} = \frac{1}{3}C_i^m + \frac{2}{3}[C_i^2 - \Delta t L(C_i^2)],$$

$$C_i^1 = C_i^m - \Delta t L(C_i^m),$$

$$C_i^2 = \frac{3}{4}C_i^m + \frac{1}{4}[C_i^1 - \Delta t L(C_i^1)],$$

$$C_i^{n+1} = \frac{1}{3}C_i^m + \frac{2}{3}[C_i^2 - \Delta t L(C_i^2)],$$

205 with  $L$  being the ~~spacial discretization~~ spatial discretisation operator:

$$L(C_i) = v_{f,i}^+ \left( \frac{C_{i+\frac{1}{2}}^L - C_{i-\frac{1}{2}}^L}{\Delta x} \right) + v_{f,i}^- \left( \frac{C_{i+\frac{1}{2}}^R - C_{i-\frac{1}{2}}^R}{\Delta x} \right).$$

With this formulation, the WENO-5 scheme is fifth order in space and third order in time.

### 3.3 Semi-Lagrangian schemes

210 Semi-Lagrangian (~~SL~~) schemes take a different approach than classical Eulerian methods and are related to tracer-based advection schemes. ~~SL~~ Semi-Lagrangian schemes aim to use the best of Lagrangian and Eulerian methods by solving the problem for particles whose trajectories pass through a fixed grid at the end of each timestep, rather than recording the full history of individual particles. They are therefore unconditionally stable. Two steps are usually required to implement SL schemes: trajectory tracing and interpolation back to the grid. In this study, a backward in time SL scheme is used for the trajectory tracing, and the quasi-monotone scheme developed by Bermejo and Staniforth (1992) for the interpolation.

#### 215 3.3.1 Trajectory tracing

The advantage of backward in time SL schemes is that the interpolant is defined from the Eulerian grid. In the case of a ~~rectilinear-regular~~ grid, this reduces the complexity of the implementation and the numerical cost of the interpolation function, since the interpolant is defined on a regular grid. From a particle point of view, the goal is to ~~find the starting points at the previous timestep for each grid point~~ retrieve the position of the particle at time  $t_n$  for which the position corresponds to a grid

220 point at time  $t_{n+1}$ . Using Eq. (5) for one chemical element and in 1D, the following ordinary differential equation has to be solved:

$$\frac{dx}{dt} = v_f(x, t). \quad (10)$$

Knowing  $x(t_{n+1}) = x_i$  with, where  $i$  a grid point,  $x(t_n) = x_d$  with, where  $d$  is a departure point that needs to be found.

In practice In most practical cases, the velocity field varies greatly in time and in space between each time-step, especially  
 225 for porosity waves, so it is not easy to determine  $x_d$ . A common approach to overcome this limit accurately determine  $x_d$  is to use the a linear multistep method such as the implicit mid-point scheme (Robert (1981)):

$$\frac{x_i - x_d}{\Delta t} = v_f\left(\frac{x_i + x_d}{2}, t_{n+\frac{1}{2}}\right), \quad (11)$$

where  $v_f$  at time  $t_{n+\frac{1}{2}}$  is obtained by taking the mean between the velocity at  $n$  and  $n+1$ . The assumption behind the mid-point rule is that the velocity remains constant at the mid-point value during each timestep. This ensures that each trajectory is  
 230 linear, with the mid-point being the average of the positions of its endpoints (Fig. 3). This method is a second-order accurate trajectory method in both space and time.

Equation (11) must be solved implicitly, because  $x_d$  is present on both sides of the equation, and therefore requires iterations. It can be achieved for  $r$  iterations in that form:

$$x_d^{r+1} = x_i - \Delta t v_f\left(\frac{x_i + x_d^r}{2}, t_{n+\frac{1}{2}}\right). \quad (12)$$

235 ~~This also requires interpolation of  $v_f$  at  $t_{n+\frac{1}{2}}$   $r$  times.~~ A minimum of 3 iterations while using linear interpolation has been shown to be sufficient in most cases (e.g., McDonald, 1984).

### 3.3.2 Interpolation

In most cases,  $x_d$  does not correspond to a stencil point on the grid grid node (see Fig. 3). In this case, interpolation is required to retrieve the value of the unknown at  $x_d$ :

$$240 \quad C(x_d, t) = \mathcal{L}[C(x_{i_k}), t],$$

where  $\mathcal{L}$  is an interpolation operator and  $x_{i_k}$  represents the nodes of the cell containing  $x_d$ .

Commonly, cubic interpolants are applied as it is used as they offer a good compromise between performance and accuracy (e.g., Chandrasekar, 2022) and require in 1D four grid points  $x_{i_k}$  per particle. Cubic B-splines are used in this study. The Godunov's theorem still applies to linear SL schemes and since cubic interpolation is third-order in space, it introduces os-  
 245 cillations and overshoots for high gradients. To overcome this limitation, quasi-monotone (QM) SL schemes were developed

**Figure 3.** Summary of trajectory tracing for backward semi-Lagrangian schemes. The aim is to find the value of the advected quantity at the position  $x_i$  and at the timestep  $t_{n+1}$ . The blue particle uses the velocity at  $n + 1$ . The yellow particle shows the midpoint method, using an approximation of the velocity at  $n + \frac{1}{2}$ . The value of the particle at position  $x_d$  can then be interpolated at  $t_n$  to obtain the value at  $x_i$  at  $t_{n+1}$ .

by Bermejo and Staniforth (1992). The term QM means that the scalar field values cannot exceed the range of the previous timestep, but can still develop wiggles inside that range. Quasi-monotonicity is equivalent to the notion of essentially non-oscillatory (Bermejo, 2001). A disadvantage of this method is an increased numerical diffusion, especially for high **Courant**  $C_o$  number. A maximum **Courant**  $C_o$  number of 1.5 is generally used (e.g., Smith, 2000).

250 To implement QMSL schemes, let's define  $C^-$  and  $C^+$  as the minimum and maximum scalar values of the nodes of the cell containing  $x_d$  and  $C^H$  as the high order non-monotone interpolant, [here a cubic spline](#). Then, a local clipping can be applied at the end of each timestep:

$$C^M(x_d, t) = \begin{cases} C^+(x_d, t) & \text{if } C^H(x_d, t) > C^+(x_d, t) \\ C^-(x_d, t) & \text{if } C^H(x_d, t) < C^-(x_d, t) \\ C^H(x_d, t) & \text{otherwise,} \end{cases} \quad (13)$$

where  $C^M$  is the quasi-monotone interpolant. Equation (13) can be rewritten in a more compact way:

255  $C^M(x_d, t) = \min \{ \max [C^-(x_d, t), C^H(x_d, t)], C^+(x_d, t) \}.$

Formally, this formulation is equivalent to a linear combination between a high order interpolant and a first order (monotone) interpolant (Bermejo, 2001).

### 3.4 Marker-in-cell schemes

~~Marker-In-Cell (MIC)~~ Marker-in-cell schemes share the same ambition as SL schemes, such as being unconditionally stable, but are closer to Lagrangian schemes. They record the complete history of individual particles, called markers and interpolate their values on a fixed grid. This approach has the advantage of ~~reducing greatly~~ greatly reducing numerical diffusion and making MIC schemes unconditionally stable. In addition to trajectory tracing and interpolation, the MIC schemes require markers to be generated within the domain of the model.

#### 3.4.1 Initial marker generation and reseeded of particles

The number of markers per cell required can vary depending on the complexity of the problem. Here, 5 markers per cell dimension, effectively 25 in 2D. This is generally sufficient to achieve good accuracy (e.g., Gerya, 2019). The initial value ~~of~~ in each marker can then be directly derived from the initial conditions or obtained by linear interpolation from the initial conditions of the Eulerian grid.

For highly divergent flows, or sometimes strongly stretching flows, it is necessary to regenerate or remove markers during the simulation, ~~as~~. For highly divergent flows, this is because particles will accumulate in zones with negative divergence values and create a gap in zones with positive divergence values. For highly stretching flow, increases or gaps in the density of the markers can be induced by preferential flow in a particular direction. For reseeded, a non-conservative strategy similar to Keller et al. (2013) is used. If the marker density per cell is less than 25% of the initial density, new markers are generated and ~~are~~ assigned the value of the nearest marker. The old markers are discarded after this step. For marker accumulation, the marker density cannot exceed twice the initial density. If it does, a quarter of the markers are discarded at random.

#### 3.4.2 Trajectory tracing

The goal of trajectory tracing for MIC schemes is to determine the position of each marker at the next timestep. The same equation as Eq. 10 is solved. However, compared to backward SL where the final position is known, the unknown in this case is the position of the arrival point at  $t^{n+1}$ . Also, the common way to solve this equation for MIC schemes is not using a linear multistep method such as the implicit midpoint scheme, but rather Runge-Kutta schemes (Gerya, 2019). Using a second-order Runge-Kutta scheme, it consists of four steps. Interpolating  $v_f$  at  $t_n$  at the departure point  $x_d$  of the markers, finding the position of the markers at  $t_{n+\frac{1}{2}}$  using  $v_f$  at  $t_n$ , reinterpolating the velocity at this new position, and using this new velocity to compute the arrival point  $x_a$  of the markers at  $t_{n+1}$  from  $t_n$ .

~~We can rewrite Eqs. 11 and 12 for the unknown  $x_a$ , the arrival point, using the mid-point rule as:~~

285 
$$\frac{x_a - x_d}{\Delta t} = v_f \left( \frac{x_a + x_d}{2}, t_{n+\frac{1}{2}} \right),$$

and

$$x_a^{r+1} = x_d + \Delta t v_f \left( \frac{x_a + x_d^r}{2}, t_{n+\frac{1}{2}} \right).$$

~~As for the SL schemes, it is necessary to interpolate the velocity field  $r$  times.~~

Since classical interpolants do not retain the physical properties of the velocity field, such as its divergence, a simple bilinear  
 290 interpolation may lead to unphysical clustering of markers on the time scale of a numerical model. To address this issue, Pusok et al. (2017) explored different interpolants and showed the advantages of using the ~~so-called~~ LinP interpolation scheme (Gerya, 2019). The LinP interpolation scheme is an empirical relationship that combines two linear interpolants defined at the sides and at the center of each cell. It is defined as:

$$v_f \left( \frac{x_a + x_d}{2}, t_{n+\frac{1}{2}} \right) = A \mathcal{L} \left[ v_f \left( x_{\text{side}}, t_{n+\frac{1}{2}} \right) \right] + (1 - A) \mathcal{L} \left[ v_f \left( x_{\text{center}}, t_{n+\frac{1}{2}} \right) \right],$$

295 with  $A$ , a constant commonly equal to  $2/3$ ,  $\mathcal{L}$  a linear interpolant, and  $x_{\text{side}}$  and  $x_{\text{center}}$  the position of the sides and center of the cell containing  ~~$x_d$~~  the marker.

Using this definition, we can rewrite the four steps of the second-order Runge-Kutta scheme in mathematical notation with four equations:

$$v_f(x_d, t_n) = A \mathcal{L}[v_f(x_{\text{side}}, t_n)] + (1 - A) \mathcal{L}[v_f(x_{\text{center}}, t_n)],$$

300 
$$x_h = x_d + \frac{1}{2} \Delta t v_f(x_d, t_n),$$

$$v_f(x_h, t_n) = A \mathcal{L}[v_f(x_{\text{side}}, t_n)] + (1 - A) \mathcal{L}[v_f(x_{\text{center}}, t_n)],$$

$$x_a = x_d + \Delta t v_f(x_h, t_n),$$

with  $x_h$ , the intermediate position of the marker. Solving these four equations successively to obtain a value for  $x_a$  with this method is second order in space but only first order in time, as only the velocity at  $t_n$  is used.

### 305 3.4.3 Interpolation

After calculating the position of the markers, it is necessary to interpolate back on the Eulerian grid. ~~This and/or to update the values of the markers from the Eulerian grid depending on the problem being solved. The step of updating the markers is not~~

described in detail here, as it is not used in this study, but involves a simple interpolant when a regular grid is used. This step is more complex than for SL schemes for updating the advected field on the Eulerian grid because the markers are not uniformly distributed for a non-trivial velocity field. Therefore, even for regular Eulerian grid contrary to SL schemes, interpolation is performed on an unstructured grid as it is based on the position of the markers.

In this case, interpolation is required to obtain the values of our unknown at  $x_i$ , where  $i$  is a grid point. In most cases, linear interpolants are used because they prevent oscillations, and the marker densities are high enough to prevent numerical diffusion. In this study, a weighted distance averaging linear interpolant is used (Gerya, 2019):

$$C(x_i, t_{n+1}) = \mathcal{L} \left[ C(x_{i_{m_k}}, t_{n+1}) \right],$$

$$w(x_m, t_{n+1}) = 1 - \frac{\Delta x_m}{\Delta x},$$

$$C(x_i, t_{n+1}) = \frac{\sum_{i=1}^m C(x_m, t_{n+1}) w(x_m, t_{n+1})}{\sum_{i=1}^m w(x_m, t_{n+1})},$$

where  $x_{i_{m_k}}$  represents the surrounding markers used for the interpolant and  $\mathcal{L}$  is an interpolation operator. Typically, all  $x_m$  is the position of a marker  $m$ ,  $\Delta x_m$  is the distance between a marker  $m$  and the grid point  $i$  and  $w$  is the weight of a marker  $m$ . All markers found in the surrounding cells surrounding grid point  $i$  are used for the interpolation (e.g., Gerya and Yuen, 2003b). Linear interpolants are used because they prevent oscillations, and marker densities are high enough to prevent numerical diffusion interpolation, as in Gerya and Yuen (2003b). The relationship between the markers and the grid is summarised on in 2D is summarised in Fig. 4 in 2D. One disadvantage of this interpolant is that it is prone to race conditions in shared memory systems, as it involves two sums, which requires the use of atomic operations to parallelise the implementation.

#### 4 Numerical tests

To test the four advection schemes, the two different numerical tests are performed in 2D: the pure rotation of a cylinder in 2D is performed. The and the advection through a more complex velocity field mimicking a convection cell. In both cases, the domain is a square of size  $1.0 \times 1.0$  with a constant spacing of  $\Delta x = \Delta y = 0.005$  for a resolution of  $201 \times 201$  nodes. The radius of the cylinder is  $24\Delta x$ , contains with a mass fraction of 1.0 and is centered at coordinates  $(0.25; 0.25)$ . The initial conditions are shown on for both tests are shown in Fig. 5.

The time increment  $\Delta t$  is set to 400 s with  $\omega = \pi \times 10^{-5} \text{ s}^{-1}$

For the first test, the time increment is  $\Delta t = 400$  with  $\omega = \pi \times 10^{-5}$  so that it takes 500 timesteps to make a full revolution. The velocity is defined as  $\mathbf{v} = (-\omega(y-0.5); \omega(x-0.5))$  so that the rotation is anti-clock wise, and the centre of it is at coordinates  $(0.5; 0.5)$ . The Courant numbers inside the cylinder range between

**Figure 4.** Sketch showing the geometric relationship in 2D between a point  $x_{i,j}$  of the Eulerian grid and the markers  $x_{m_k}$  used for the interpolation on a regular grid. The value at the point  $x_{i,j}$  is interpolated from the markers  $x_{m_k}$  contained inside the four neighbouring cells.  $x_{i,j}$  is fixed in time and in space, whereas the position of the markers  $x_{m_k}$  are time-dependent.

0.45 and 0.8. Results-The test is stopped after 2 revolutions are shown on Fig. 6 for the four schemes. For the second test,  $v$  is defined as  $v = (-2\pi \times \sin(\pi x) \times \cos(\pi y); 2\pi \times \cos(\pi x) \times \sin(\pi y))$ . The time increment  $\Delta t$  is fixed by constraining the  $Co$  number to be 0.7 for a total time of 0.8 and 1016 timesteps. At half of the total time, the opposite sign of  $v$  is taken as the new value of  $v$ , such that the analytical solution of the problem corresponds to the initial conditions.

340 To compare and quantify the results of the different schemes, 4 different the following quantities were monitored: the mass conservation ( $M$ ), the total error ( $E_{tot}$ ), the maximum value of the final mass fraction ( $\max(C_f)$ ) and the minimum elapsed computational time of 1 timestep ( $t_{scheme}$ ) one timestep after 10000 runs, with one thread and with 24 threads.

The mass conservation is defined as:

$$M = \frac{\sum_{k=1}^K (C_f^k S_k)}{\sum_{k=1}^K (C_0^k S_k)}, \quad (14)$$

345 where  $k$  is a 2D grid point index,  $K$  is the total number of grid points,  $C_f^k$  is the final mass fraction at the index  $k$  and  $C_0^k$  is the initial mass fraction at index  $k$  and  $S_k$  is the surface area of the cell at index  $k$ .

**Figure 5.** Initial conditions for the two numerical test consisting of the rotation of a cylinder tests. The yellow arrows show the velocity field fields of the tests. (a) Rotation of a cylinder. (b) Convection of a cylinder using a parametrisation of Lorenz equations.

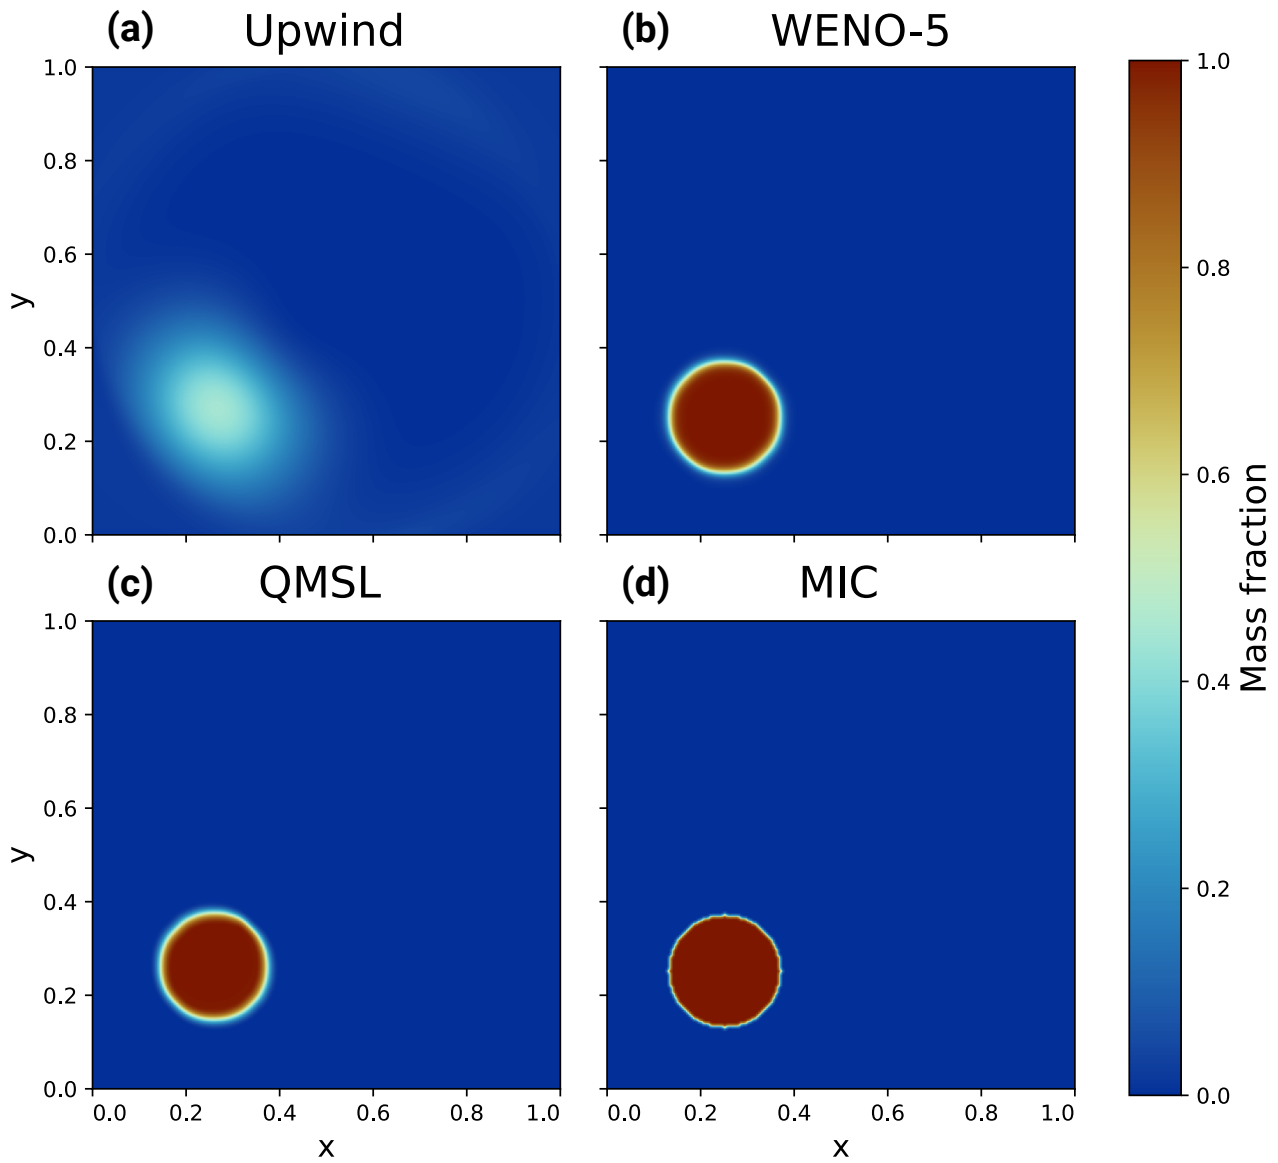

The total error of the scheme is defined as the mean square error:

$$E_{\text{tot}} = \frac{1}{K} \sum_{k=1}^K (C_0^k - C_f^k)^2.$$

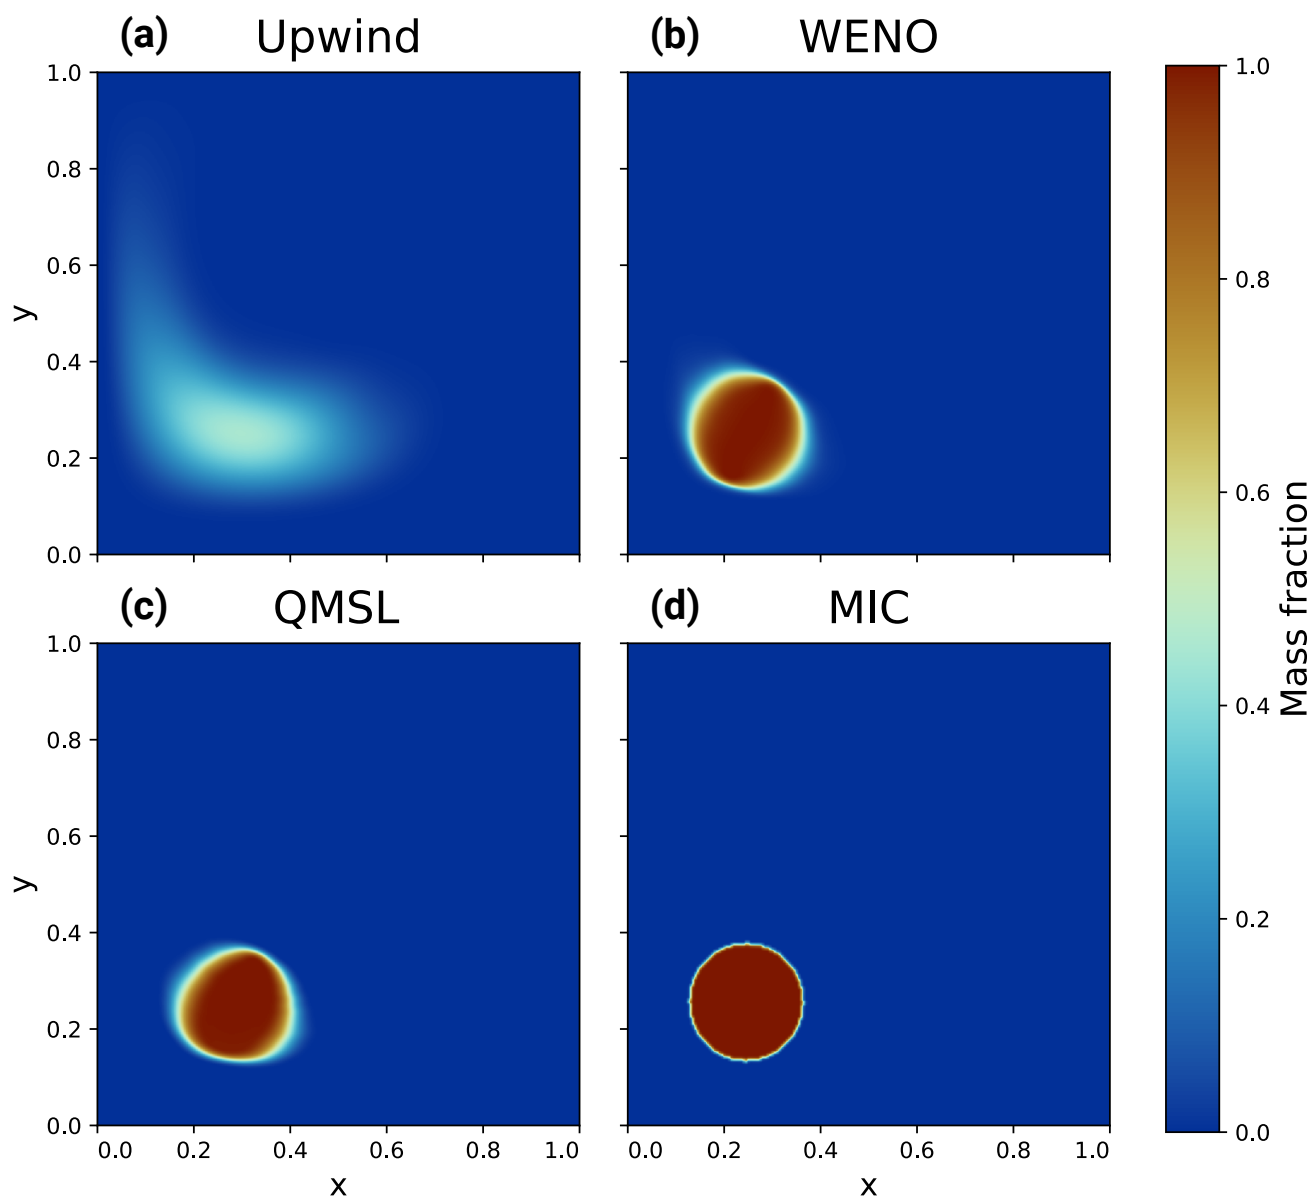

The results for both tests are reported in Table 2 -This shows the and on Figs. 6 and 7 for the four different schemes. Both tests show the strong numerical diffusion of the upwind scheme and its high  $E_{\text{tot}}$  due to its first order in time and space. The WENO-5 scheme shows no oscillation and a good accuracy, being fifth order in space and third in time -SL-QM in both tests, with a small mass loss in the second test. The QMSL is not mass conservative for this problem but show both problems. It shows a relatively good accuracy, being third order in space and second in time and is monotone, is monotone but shows deformation of the original cylinder at the end of the second test. Finally, for this test both tests, the MIC scheme is mass conservative, monotone and shows the best accuracy -This simple test highlights with almost no numerical diffusion. These simple tests highlight the properties of each scheme, but uses-use a velocity field that is divergence-free and without sharp variations. This is not the case for a real case problem. Coupling with a two-phase flow system is therefore necessary to assert which scheme is the more suitable in this case.

## 5 Coupling chemical advection and two-phase flow

360 Solving Eq. (5) for concrete cases implies having an expression for  $v_f$  at each timestep. In this section, Eq. (5) is coupled to a transport model based on two-phase flow formalism. This transport model is used to model magma ascent in a porous solid

**Figure 6.** Results of the rotational test after two revolutions for the upwind, WENO-5, ~~SL-QM~~ QMSL and MIC schemes (a)-(d). Note that the upwind scheme was run with  $\Delta t = 80$  ~~\*~~  $\Delta t = 80$  due to stability issues.

**Figure 7.** Results of the convection test after a total time of 0.8 for the upwind, WENO-5, QMSL and MIC schemes (a)-(d). The velocity field was reversed at half of the total time so that the anomaly returns to its initial position.

**Table 2.** Results of the two numerical tests for four advection schemes. [The running time for the MIC doesn't include the reseeding and removal step of markers.](#)

Numerical schemes	Rotational test			Convection test			Running time of one

phase. The main mechanism of transport is decompaction weakening, buoyancy and failure, and combines the formulations of Connolly and Podladchikov (2007a) and Vasilyev et al. (1998). It considers a compressible visco-elastic matrix with incompressible solid grains and an incompressible fluid phase, and neglects the effect of shear stresses on fluid flow and compaction.

### 365 5.1 Two-phase Flow Formulation [flow formulation](#)

In the case of a laminar fluid flow, conservation of momentum for the fluid can be expressed using Darcy's law:

$$\phi(\mathbf{v}_f - \mathbf{v}_s) = -\frac{k(\phi)}{\mu_f}(\nabla P_f + \rho_f \mathbf{g}), \quad (15)$$

with  $P_f$  the fluid pressure (in Pa),  $k$  the permeability ( $\text{m}^2$ ), a function of the filled porosity [or melt fraction](#)  $\phi$ ,  $\mu_f$  the fluid viscosity (Pa.s), and  $\mathbf{g}$  the gravity vector ( $\text{m.s}^{-2}$ ).

370 The relation between permeability and [the filled](#) porosity is assumed to follow the Kozeny-Carman law (Carman, 1939; Costa, 2006):

$$k = a\phi^3,$$

where  $a$  is a proportionality constant.

The effective pressure  $P_e$  is defined as the difference between lithostatic pressure and fluid pressure:

$$375 P_e = P_{\text{lith}} - P_f, \quad (16)$$

with  $P_{\text{lith}}$  the lithostatic pressure or the vertical load (in Pa). Substituting Eq. (16) in Eq. (15) and assuming constant rock density, we obtain:

$$\phi(\mathbf{v}_f - \mathbf{v}_s) = \frac{k(\phi)}{\mu_f}(\nabla P_e + \Delta\rho\mathbf{g}). \quad (17)$$

Considering the solid phase as a Maxwell body, we introduce rheology as the sum of viscous and poro-elastic deformation:

$$380 \quad \nabla \cdot \mathbf{v}_s = -\frac{P_e}{\zeta(\phi, P_e)} - \phi^b \beta_\phi \frac{\partial P_e}{\partial t}, \quad (18)$$

where  $\zeta$  is the volume viscosity of the rock (in Pa.s),  $b$ , a constant, and  $\beta_\phi$  the pore compressibility modulus (Pa<sup>-1</sup>). The terms on the right-hand side represent viscous and poro-elastic deformation, respectively. Equation (18) is valid on the basis that shear stress is neglected.

The volume viscosity  $\zeta$  is defined as a function of  $\phi$  and  $P_e$ :

$$385 \quad \zeta = \frac{\mu_s}{\phi^m} \left[ \frac{1}{R} - H(P_e) \left( \frac{1}{R} - 1 \right) \right],$$

with  $\mu_s$  the shear viscosity of the rock (in Pas),  $m$  a constant, and  $R$  the decompaction weakening factor, defined as the inverse of the  $R$  factor in Connolly and Podladchikov (2007a).  $H(P_e)$  is originally defined as the Heaviside function but is here approximated by a hyperbolic tangent function as similarly done by Räss et al. (2018).

We approximate here  $\beta_\phi$  as the inverse of  $G$ , the shear modulus of the rock (in Pa):

$$390 \quad \beta_\phi \approx \frac{1}{G}.$$

This is valid for cylindrical pores, as described by Yarushina and Podladchikov (2015).

Summing up the right-hand sides of Eqs. (1) and (2) describing mass conservation and neglecting the change of densities, we obtain the total volumetric flux of material. Applying the divergence operator, we can derive:

$$\nabla \cdot [\mathbf{v}_s + \phi(\mathbf{v}_f - \mathbf{v}_s)] = 0. \quad (19)$$

395 We can then substitute Eqs. (17) and (18) in Eq. (19) to obtain:

$$\frac{P_e}{\zeta(\phi, P_e)} + \frac{\phi^b}{G} \frac{\partial P_e}{\partial t} = \nabla \cdot \left[ \frac{k(\phi)}{\mu_f} (\nabla P_e + \Delta \rho \mathbf{g}) \right]. \quad (20)$$

In addition, developing Eq. (1) with the assumption that  $\phi$  is much smaller than unity, and substituting with Eq. (18) yields:

$$\frac{\partial \phi}{\partial t} = -\frac{P_e}{\zeta(\phi, P_e)} - \frac{\phi^b}{G} \frac{\partial P_e}{\partial t}. \quad (21)$$

400 Equation (20) can be seen as the mass conservation equation of the system, relating the flux densities of the solid and fluid phases. Equation (21) relates the evolution of porosity with the deformation of the solid phase.

Solving these two coupled equations for  $P_e$  and  $\phi$  allows the calculation of  $\mathbf{v}_s$  and  $\mathbf{v}_f$  from Eqs. (18) and (17) at each timestep, making the link with Eq. (5).

## 5.2 ~~Nondimensionalization~~ Nondimensionalisation and numerical approach

To mitigate numerical errors, a dimensionless scaling of the system is applied. ~~We define the following scaling variables~~  
 405 ~~(McKenzie, 1984; Connolly and Podladchikov, 1998)~~

~~the characteristic porosity  $\phi^*$ :~~

$$\underline{\phi^* = \phi_0,}$$

~~with  $\phi_0$ , the background porosity.~~

~~The characteristic viscous compaction length  $L^*$ :~~

$$410 \underline{L^* = \sqrt{\frac{\mu_s k_0}{\phi_0 \mu_{f0}}},}$$

~~with  $k_0$ , the background permeability (in  $\text{m}^2$ )~~

~~The characteristic effective pressure  $P_e^*$ :~~

$$\underline{P_e^* = L^* \Delta \rho g.}$$

~~The characteristic fluid flux  $q_f^*$ :~~

$$415 \underline{q_f^* = \frac{\mu_{f0}}{\phi_0} \Delta \rho g L^* .}$$

~~The characteristic time  $t^*$ :~~

$$\underline{t^* = \frac{L^*}{\sqrt{q_f^*}}.}$$

~~$De$ , the Deborah number:~~

~~$De$  is formally the ratio of the relaxation time to the observation time (Reiner, 1964), and here characterises the ratio between  
 420 viscous and elastic deformation.~~

~~Using these~~ The scaling variables are defined in Table 3. Using the scaling variables with Eqs. (17), (18), (20) and (21), and rearranging, we obtain the dimensionless system of equations:

$$\underline{\frac{\partial p}{\partial t} \frac{\partial p}{\partial t_e} = \frac{1}{\varphi^b De} \times \left( \nabla \cdot [\varphi^n (\nabla p + 1)] - \frac{\varphi p}{\frac{1}{R} - H(p)(\frac{1}{R} - 1)} \right)}, \quad (22)$$

**Table 3.** Parameters and corresponding scaling variables used in the models. Definition of the scaling variables are from McKenzie (1984); Connolly and Podladchikov (1998).

Parameter	Symbol	Definition	Value	Unit
Melt viscosity	$\mu_t$		100	Pa.s
Rock shear viscosity	$\mu_s$		$10^{19}$	Pa.s
Density contrast between solid and melt	$\Delta\rho$		500	$\text{kg.m}^{-3}$
Weakening parameter	$R$		100	
Shear modulus	$G$		$3.5 \times 10^9$	Pa
Background porosity	$\phi_0$		$10^{-3}$	
Permeability constant	$a$		$10^{-7}$	$\text{m}^2$
Background permeability	$k_0$		$a \phi_0$	$\text{m}^2$
Exponent for bulk viscosity term	$m$		1	
Exponent for poro-elastic term	$b$		1	
Gravity acceleration	$g$		9.80665	$\text{m.s}^{-2}$
Characteristic porosity	$\phi^*$	$\frac{\phi_0}{\phi_0 t_{f0}}$	$10^{-3}$	
Characteristic viscous compaction length	$L^*$	$\sqrt{\frac{\mu_s k_0}{\phi_0 t_{f0}}}$	100	m
Characteristic effective pressure	$P_e^*$	$L^* \Delta\rho g$	490332.5	Pa
Characteristic fluid flux	$q_f^*$	$\frac{\mu_{f0}}{\phi_0} \Delta\rho g L^*$	$4.9 \times 10^{-12}$	$\text{m.s}^{-1}$
Characteristic time	$t^*$	$\frac{L^*}{q_f^*}$	0.65	Myr
Deborah Number	$De$	$\beta_\phi P_e^*$	$1.4 \times 10^{-5}$	

$$\frac{\partial \varphi}{\partial t} \frac{\partial \varphi}{\partial t_e} = - \left[ \frac{\varphi p}{\frac{1}{R} - H(p)(\frac{1}{R} - 1)} + \varphi^b De \frac{\partial p}{\partial t} \frac{\partial p}{\partial t_e} \right], \quad (23)$$

$$425 \quad \nabla \cdot \mathbf{u}_s = \frac{\partial \varphi}{\partial t} \frac{\partial \varphi}{\partial t_e}, \quad (24)$$

$$\mathbf{u}_f = \varphi^{n-1} (\nabla p + 1) + \mathbf{u}_s, \quad (25)$$

where  $\varphi$ ,  $p$ ,  $t_{cs}$ ,  $\mathbf{u}_s$  and  $\mathbf{u}_f$  are the dimensionless porosity, the dimensionless effective pressure, the dimensionless time, the dimensionless solid velocity and the dimensionless fluid velocity, respectively. The Deborah number  $De$  is formally the ratio of the relaxation time to the observation time (Reiner, 1964), and here characterises the ratio between viscous and elastic deformation. In the limit of small porosities,  $\mathbf{u}_s$  can be neglected and only eqs. (22), (23) and (25) are here solved.

430

Equations (22) and (23) are strongly coupled and highly stiff due to the nonlinearity of the system and require an efficient numerical solver. DifferentialEquations.jl (Rackauckas and Nie, 2017), a robust ordinary differential equation (ODE) solver package, was used. This method package has the advantage of simplicity, both in concept and in coding, and allows arbitrary orders of accuracy in time to be easily tested using different ODE solvers.

435 Equations (22) and (23) are first discretised in space using finite differences on a uniform Cartesian grid in 2D, and then integrated in time using the Trapezoidal Rule trapezoidal rule with the second order Backward Difference Formula backward difference formula (TR-BDF2) scheme, an implicit scheme suitable for highly stiff problems (Bank et al., 1985) using DifferentialEquations.jl. It uses adaptive time-stepping and Newton method as a non-linear solver, using forward automatic differentiation to compute the Jacobian matrix (Revels et al., 2016). Knowing  $\varphi$  and  $p$ , Eqs. (24) and (25) are (25) is then  
 440 solved to compute  $u_s$  and  $u_f$  at each timestep. The boundary conditions are periodic in all directions for all models. The system is then dimensionalised back.

### 5.3 Application to magmatic system

To assert-assess the behaviour of the four advection schemes coupled with a two-phase flow system, we model the ascent of a magmatic anomaly. The spatial domain is a 2D regular grid of 450 by 900 m and the total physical time is 1.5 MaMyr. The  
 445 initial melt fraction distribution is defined using the following 2D Gaussian function:

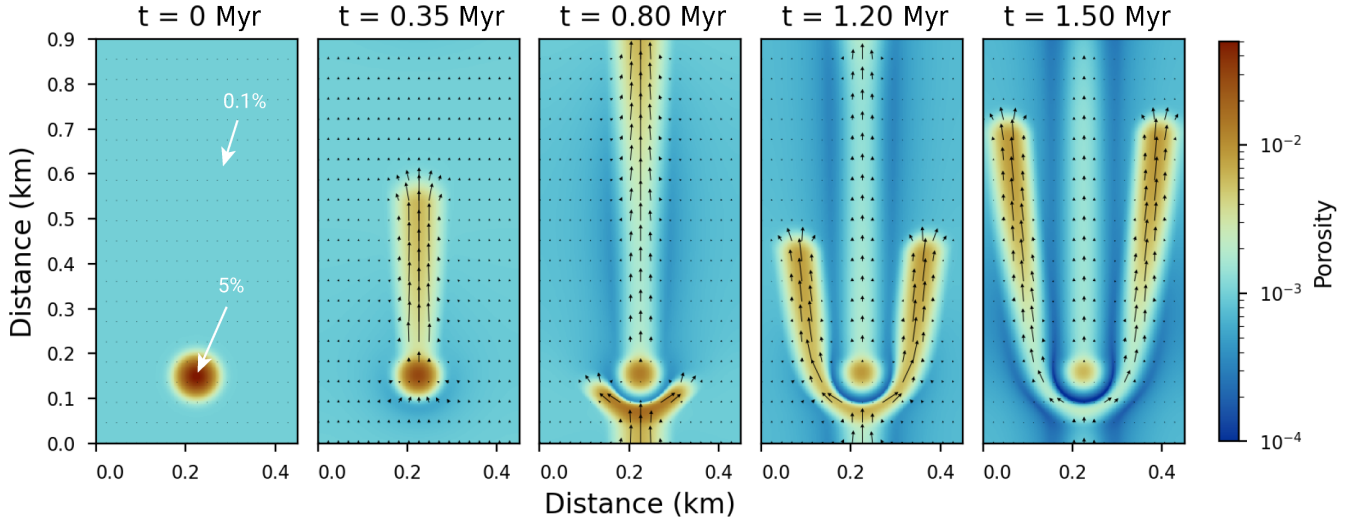

$$\phi = \phi_0 + \phi_{max} \times \exp\left(-\frac{(x - x_0)^2 + (z - z_0)^2}{\sigma^2}\right),$$

with  $\phi_0$ , the background porosity defined as 0.1%,  $\phi_{max}$ , the maximum porosity defined as 5%, and  $x_0$  and  $z_0$ , the center of the anomaly. The standard deviation  $\sigma$  is the standard deviation of the Gaussian and is 30. is 30 m. All physical parameters and corresponding scaling variables used are reported in Table 3. The evolution of porosity is shown on Fig. 8. All models were  
 450 performed on a single computer with an Intel Xeon Gold 6128 processor and 128 GB of RAM using Julia version 1.10.2. All models were computed on CPU with multithreading using 24 threads.

Parameters and corresponding scaling variables used in the models: Parameter Symbol Value Unit Melt viscosity  $\mu_f$  100 Rock shear viscosity  $\mu_s$   $10^{19}$  Density contrast between solid and melt  $\Delta\rho$  500 Weakening parameter  $R$  100 Shear modulus  $G$   $3.5 \times 10^{19}$  Background porosity  $\phi_0$   $10^{-3}$  Exponent for bulk viscosity term  $m$  1 Exponent for poro-elastic term  $b$  1 Permeability constant  $a$   $10^{-7}$  Gravity acceleration  $g$  9.81 Characteristic viscous compaction length  $L^*$  100 Characteristic effective pressure  $P_e^*$  490332.5 Characteristic time  $t^*$  0.65 Characteristic fluid flux  $q_f^*$   $4.9 \times 10^{-12}$  Deborah Number  $De$   $1.4 \times 10^{-5}$

The melt fraction is linked-associated with two different arbitrary chemical compositions: a basaltic composition for the background melt fraction and an andesitic composition for the anomaly. The goal, corresponding to a circle with a radius of  
 460 60 m. The aim is not to model a realistic magmatic system, but to investigate how the advection schemes can numerically affect the predictions of the model. The two compositions are reported in Table 4. No feedback between the melt compositions and the physical properties of the melt were considered, to prevent the advection schemes to influence on the two-phase flow. In nature, the real settings, the effect of melt composition on melt composition has an effect on the melt viscosity and density is

**Figure 8.** Reference evolution of the porosity in a 2D model from an initial Gaussian anomaly, which forms porosity waves. The superimposed vector field shows the melt velocity. Periodic boundaries are applied on all sides. The initial porosity anomaly is a Gaussian function with a maximum value of 5%. The background porosity is 0.1%. The spatial resolution of the grid is  $300 \times 600$ . The physical parameters used are listed in Table 3. The melt velocity is scaled by relative magnitude.

not negligible for these conditions. The maximum timestep allowed for the two-phase flow is constrained by the Courant- $C_o$  number associated with the melt velocity. Its maximum value allowed for upwind and the upwind and the WENO-5 is 0.7 but  
465 a value of 0.7 and 1.5 for QMSL and MIC the QMSL and the MIC were both used to take advantage of the extended stability of these schemes. The results for the evolution of the silica content in the melt are shown on Fig. 9 for the  $C_o$  number of 0.7 and for the four algorithms at a resolution of  $500 \times 1000$ .

As there is no analytical solution to this particular problem, it is not possible to directly calculate the numerical error of the different advection schemes. Nevertheless, we can compute the mass conservation of the advected quantities. The total mass  
470 of the melt composition is conserved, as it is renormalized to 100% at each timestep. This is a constant-sum constraint and is characteristic of compositional data (Aitchison, 1982). However, it is not necessary the case for each individual oxide. In that light, similar to Eq. (14), we monitor the mass conservation of  $\text{SiO}_2$  ( $M_{\text{SiO}_2}$ ) each individual oxide  $M_{\text{ox}}$  in the melt at each timestep:

$$M_{\text{SiO}_2 \text{ ox}} = \frac{\sum_{k=1}^K (\phi^k C_{\text{SiO}_2}^k S_k)}{\sum_{k=1}^K (\phi_0^k C_{\text{SiO}_2}^k S_k)} \frac{\sum_{k=1}^K (\phi^k C_{\text{ox}}^k)}{\sum_{k=1}^K (\phi_0^k C_{\text{ox}_0}^k)},$$

**Figure 9.** Evolution of the silica content in the melt for four different advection schemes: the upwind, the WENO-5, the QMSL and the MIC (a)-(d). The Gaussian anomaly of porosity is associated with an andesitic composition, whereas the background porosity has a basaltic composition. The corresponding two-phase flow has an adaptive timestep limited to a maximum value of Courant number below 0.7 for the upwind and WENO-5 schemes and below 1.5 for QMSL and MIC algorithms. The spatial resolution is  $300 \times 500 \times 600 \times 1000$  nodes. The physical parameters used for the two-phase flow are reported in Table 3 and are identical for all models.

**Table 4.** Melt compositions in wt% used in the models. 1: Recalculated from Giordano and Dingwell (2003). 2: Recalculated from Neuville et al. (1993).

Oxide (wt%)	Basalt <sup>1</sup>	Andesite <sup>2</sup>
SiO <sub>2</sub>	48.32	59.87
TiO <sub>2</sub>	1.65	0.82
Al <sub>2</sub> O <sub>3</sub>	16.72	16.93
FeO(T)	10.41	5.28
MgO	5.31	3.28
CaO	10.75	5.70
Na <sub>2</sub> O	3.85	3.76
K <sub>2</sub> O	1.99	1.36
H <sub>2</sub> O	1.00	3.00

475 where  $\phi^k$  and  $\phi_0^k$  are the current and initial porosity at index  $k$ , and  $C_{SiO_2}^k$  and  $C_{SiO_2}^k$   $C_{ox}^k$  and  $C_{ox}^k$  the current and initial ~~SiO<sub>2</sub> composition~~ composition of the oxide of interest in the melt at the index  $k$ .

The melt fraction  $\phi$  is conserved through the models, as Eqs. (22) and (23) are solved using a conservative discretisation. Therefore,  $M_{SiO_2}$   $M_{ox}$  only monitors the effects of the advection schemes for the oxide of interest. To quantify how the mass conservation evolves for each individual oxide and for each advection algorithm, the same model was performed at five  
480 different resolutions: 100×200, 200×400, 300×600, 400×800 and 500×1000. The values of  $M_{SiO_2}$  the mass conservation of silica content  $M_{SiO_2}$  for each resolution are shown on Fig. 10. ~~The~~ for all the models. The values of the mass conservation of each oxide for all the algorithms are shown on Fig. 11. The total running time of each model is reported on Fig. 12.

## 6 Results and discussion

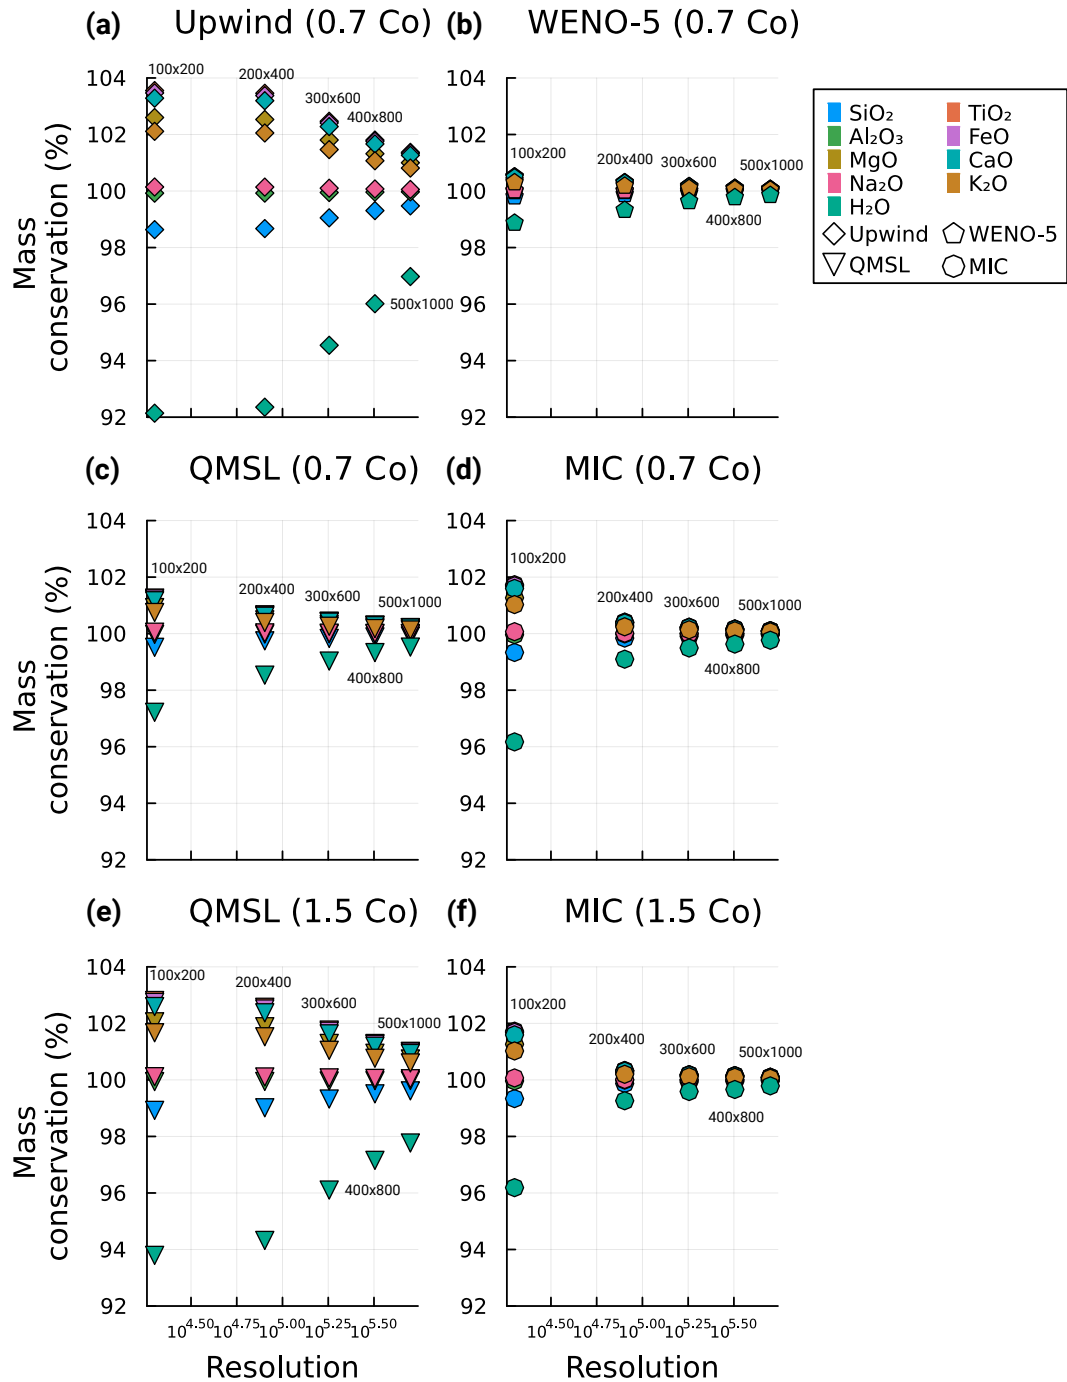

The numerical models produced allow a better understanding of the process of passive chemical transport in magma within  
485 porosity waves and the impact of each advection scheme on the magma composition over time. All models confirm two distinct composition domains at the top of the porosity waves at the end of the simulations (Fig. 9). It is effectively a mixture-mixing of the compositions from the initial background porosity and from the anomaly. This is ~~due to melt being~~ because melt is incorporated by the waves as they rise. ~~This is attributed to the velocity of the porosity waves being greater than that of the melt~~ and has also been reported in previous studies (e.g., Jordan et al., 2018).

490 Comparing the results of the four algorithms, it is clear that the upwind scheme has the highest amount of numerical diffusion ~~and the lowest accuracy~~, which increases chemical mixing for non-physical reasons. The WENO-5 and QMSL exhibit similar results in terms of numerical diffusion ~~while~~, while the MIC shows the lowest amount with almost purely advective behaviour (Fig. 9). This is consistent with the numerical tests (~~Fig. 6~~ Figs. 6 and 7). In terms of mass conservation, the silica oxide content is not conserved in all four schemes (~~Fig. 10~~ Figs. 10 and 11). The WENO-5 gives the best results, with a mass

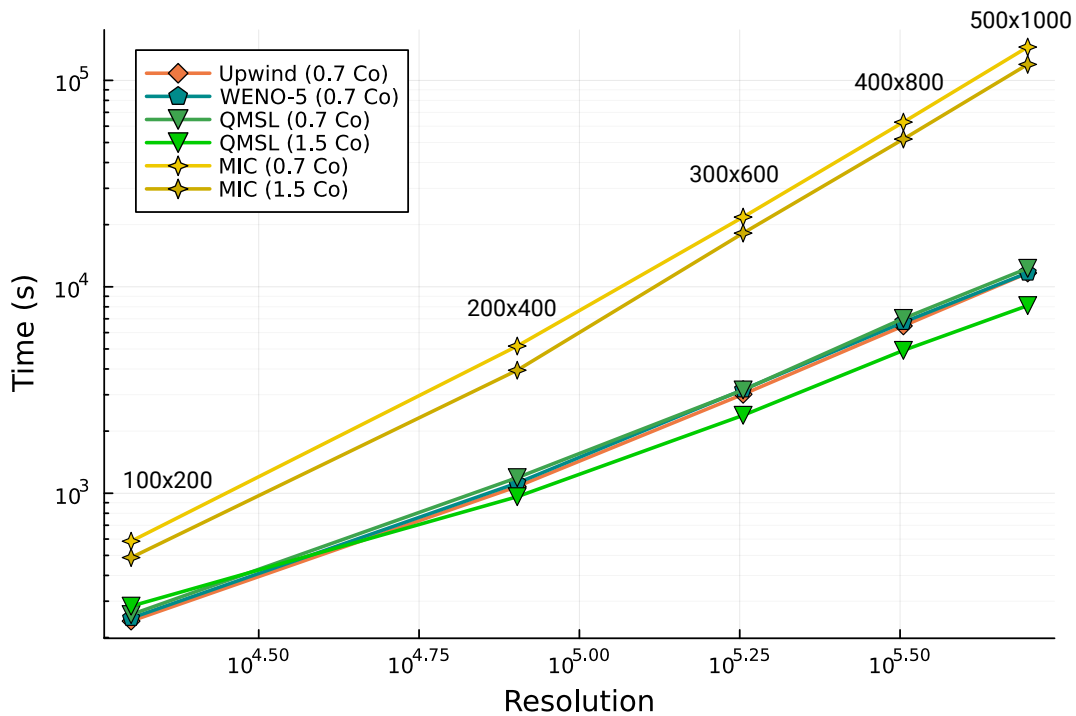

**Figure 10.** Mass conservation of silica content in the melt fraction for four different advection schemes and five different spatial resolutions at the end of each simulation. The Courant number used is 0.7 for the WENO-5 and the upwind and 0.7 or 1.5 for the QMSL and the MIC. The resolutions are 100×200, 200×400, 300×600, 400×800 and 500×1000. MIC models for 400×800 and 500×1000 were not performed due to RAM memory saturation. The physical parameters used are reported in Table 3.

495 conservation ranging from 99.75 to 99.99% from the lowest for the lowest resolution to 99.85 to 100.06% at the  
highest resolution. MIC and upwind show values around 98.5% for all the oxides. The MIC performs similarly at high resolution,  
ranging from 99.77 to 99.5% at medium resolution, and QMSL exhibits significantly lower values 100.11% for all the oxides  
at the highest resolution and with a significant increase in mass conservation from the 200x400 resolution. An improvement in  
the mass conservation for a  $Co$  number of 1.5 compared to the value of 0.7 is also noticeable. The QMSL shows slightly lower  
500 mass conservation for a  $Co$  of 0.7, ranging from 97.17 to 98.49%. Concerning performance, two factors affect the results: the  
stability of 99.52 to 100.22% at the highest resolution and 97.22 to 101.26% at the lowest. In contrast to the MIC, there is  
significant decrease for the mass conservation for a  $Co$  number of 1.5, ranging from 97.22 to 102.81% at low resolution to  
up to 97.77 to 101.01% at high resolution. The upwind scheme shows the worst values for mass conservation, ranging from  
92.14 to 103.55% at low resolution to values of 96.97 to 101.37% at the highest resolution (Figs. 10 and 11). The better mass  
505 conservation of the MIC for a higher  $Co$  number can be explained by less re seeding and removal of markers, as the approach  
used is not mass conservative. On the other hand, the advection schemes, that is linked on how often the two-phase flow solver  
is called, and the performance of the advection schemes themselves (Fig. 12). QMSL shows the best scaling as it has both

**Figure 11.** [Mass conservation of each oxide in the melt fraction for four different advection schemes and five different spatial resolutions at the end of each simulation. The Courant number used is 0.7 for the WENO-5 and the upwind \(a\)-\(b\) and 0.7 or 1.5 for the QMSL and the MIC \(c\)-\(f\). The resolutions are  \$100 \times 200\$ ,  \$200 \times 400\$ ,  \$300 \times 600\$ ,  \$400 \times 800\$  and  \$500 \times 1000\$ . The physical parameters used are reported in Table 3.](#)

**Figure 12.** Total running time of the two-phase flow system coupled with four different advection schemes and five different resolutions. The Courant number used is 0.7 for the WENO-5 and the upwind, and both 0.7 and 1.5 for the QMSL and the MIC. The resolutions are  $100 \times 200$ ,  $200 \times 400$ ,  $300 \times 600$ ,  $400 \times 800$  and  $500 \times 1000$ . MIC models for  $400 \times 800$  and  $500 \times 1000$  were not performed due to RAM memory saturation. The physical parameters used are reported in Table 3. All models were performed using a single computer with an Intel Xeon Gold 6128 processor and 128 GB of RAM using Julia version 1.10.2. All advection algorithms were computed on CPU with multithreading using 24 threads.

an extended stability domain and a low computational cost. upwind shows similar performance despite being bounded by the Courant condition. poorer performance concerning the QMSL at higher  $Co$  number can be interpreted as showing the decrease in accuracy of the trajectory tracing with increasing timestep. The differences of mass conservation observed in the different oxides through all the models show that the initial conditions play a role and that higher values in the anomaly at the beginning of the model leads to a loss of mass (e.g.  $\text{SiO}_2$  or  $\text{Al}_2\text{O}_3$ ), whereas the opposite leads to an excess of mass (e.g.  $\text{CaO}$  or  $\text{K}_2\text{O}$ ). Also, the greater the relative difference between the composition of the oxide from the anomaly and the background melt fraction, the greater the mass conservation loss or gain (e.g.  $\text{H}_2\text{O}$  or  $\text{FeO}$ ). However, it is observed that the mass conservation of all the oxides appears to converge towards 1 with increasing resolution for all methods.

In terms of performance, all schemes, except the MIC, show a runtime of the same order of magnitude for a  $Co$  number of 0.7 at all resolutions. This is due to its very simple algorithm. WENO-5 has a higher computational cost, up to twice that of QMSL and upwind at high resolution. Finally, MIC is the most computationally expensive, both in terms of memory and

520 ~~running time, although it has an~~ explained by the multithreading approach, which allows high performance, even for more  
computationally expensive algorithms due to parallelism. The high computational cost of the MIC is mainly attributed to the  
reseeding and removal of the markers, due to the highly divergent velocity field. This part was not fully parallelised due to  
race conditions caused by the removal and addition of memory at run-time. Also, the MIC and QMSL perform better for a  $Co$   
number of 1.5 compared to 0.7 (Fig. 12). This is explained by a larger adaptive timestep used by the two-phase flow solver  
due to the extended stability domain, which means that fewer time steps are required to solve the system. All the calculations  
525 were performed on a single ~~core~~ CPU and the code could be further optimised, ~~but this especially for the MIC. However, this~~  
~~result~~ provides an idea of the cost of each method. ~~For large-scale computations, the extended stability domain may be the~~  
~~dominant criterion for efficient computation, as all the advection schemes are explicit, don't require iterations and are easily~~  
~~parallelizable. The two-phase flow solver will then be the limiting factor in computational efficiency when parallelised, and~~  
530 ~~marker removal.~~

The upwind scheme is considered inadequate for this problem ~~because of~~ due to its high numerical diffusion ~~and low~~  
~~accuracy,~~ and its lack of mass conservation for highly divergent velocity fields. The MIC scheme shows very good re-  
sults in terms of accuracy with the least amount of numerical diffusion and has no stability condition. ~~It also demonstrates~~  
~~better mass conservation with a higher time-step.~~ However, it ~~lacks mass conservation and~~ is expensive in terms of com-  
535 putation and memory, ~~since as~~ it needs to keep track ~~on of~~ the markers. As the velocity field  $v_f$  is strongly divergent, it  
requires to frequently regenerate and delete markers, which adds complexity to the implementation and additional numerical  
cost. As a result, we consider this scheme to be too costly for this particular problem. ~~In addition~~ but recognise its robust  
~~qualities for other geodynamic problems where diffusion is not acceptable, such as thermomechanical deformation or mantle~~  
~~convection (e.g., Duretz et al., 2011; Ueda et al., 2015; Trim et al., 2020). On the other hand,~~ the QMSL scheme shows very  
540 good performance with its extended stability field and good accuracy, but has very poor mass conservation. ~~Attempts have~~  
~~been made to make SL schemes mass conservative, either globally (e.g., Bermejo and Conde, 2002; Zerroukat et al., 2002) or~~  
~~locally (e.g., Qiu and Shu, 2011). These methods require the conservative form of the advection equation, a global correction~~  
~~term or are only applicable to divergent free vector fields. The QMSL scheme could be a good candidate for problems where~~  
~~mass conservation is not critical, such as advection of solid properties or solving the advection part of the heat equation, still~~  
545 ~~in the context of two-phase flow problems but is not suitable for chemical advection where mass conservation is important.~~

~~Based on~~ for a high  $Co$ , which contradicts the purpose of this scheme. A potential approach to improve the mass conservation  
~~would be to improve the trajectory tracing step, either by using higher-order multistep methods (e.g., Filbet and Prouveur, 2016)~~  
~~or by using Runge-Kutta schemes, similar to the one used for the MIC. On the basis of~~ these results, the WENO-5 advection  
scheme appears to ~~perform best~~ be the most appropriate for this problem. Mass conservation is a critical property for studying  
550 mass balance and mass transport problems ~~linked to~~ associated with magma transport at different scales on Earth, and this  
algorithm obtains the best results. It also has good accuracy, reasonable performance ~~and~~, is easy to extend to higher dimen-  
sions. ~~If complex boundary conditions are required, it is possible to reduce the 5-point spatial stencil to a 3-point stencil and~~  
~~simplify the implementation of the boundary conditions, using the Compact-Reconstruction WENO-5 (CRWENO-5) scheme~~

(Ghosh and Baeder, 2012). This approach uses implicit candidate stencils, which makes parallel computing more difficult but not impossible (Ghosh et al., 2015). and to parallelise.

## 7 Conclusions

In this study, a series of ~~test was performed~~ tests were carried out to determine which advection ~~schemes~~ scheme is the most suitable for modelling chemical transport of a magma, ~~we compared four~~. Four of the most commonly used algorithms in the literature were compared: the upwind, WENO-5, MIC, and QMSL schemes. To test them, we combined a 2D two-phase flow model, which describes the evolution of the melt fraction of a magma over time, with the chemical advection of its composition.

All algorithms, ~~except the~~ with the exception of the upwind scheme, are able to predict the melt composition with reasonable accuracy. However, mass conservation of each individual oxide in the melt is not fully achieved. Nevertheless, the WENO-5 ~~has the lowest amount of mass loss~~ scheme shows the best results in mass conservation, even at low ~~resolution~~ resolutions, is explicit, easy to implement and ~~to~~ extend in 3D, although it is bound-constrained by the CFL condition. ~~On the basis of~~ Based on these results, the WENO-5 scheme is the most appropriate ~~suitable~~ to use for transporting magma composition during magma ascent. This is also ~~valid for~~ applicable to problems using similar formulations, such as chemical advection in aqueous fluids, and makes WENO-5 a suitable scheme for modelling reactive transport in crustal or mantle conditions.

*Author contributions.* HD and PL conceptualised the project. PL acquired the funding. HD conducted the study with input from NR. HD wrote the code and the original manuscript. NR and PL revised and edited the manuscript. All authors contributed to the discussions and interpretation of the results.

*Competing interests.* The contact author has declared that none of the authors have competing interests.

*Acknowledgements.* HD thanks Thibault Duret and Ludovic Räss for discussion on the MIC implementation and the two-phase flow, respectively. The authors are grateful to Marcin Dabrowski and Albert de Montserrat Navarro for their thorough and constructive review of the original draft, which improved the quality of this study. Funding was provided by the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grant agreement No 850530).
