31 Abstract. This study focuses on the uncertainties that influence numerical simulation results of
32 meteorological fields (including horizontal resolution: 75 km, 15km and 3 km, vertical resolution:
33 48 and 62 levels, near-surface (N-S) scheme: MM5 and Eta schemes, initial and boundary conditions:
34 Final (FNL) and European Center for Medium-Range Weather Forecasting (ECMWF) reanalysis
35 data, underlying surface update: model default and latest updates, and update of model version:
36 version 3.6.1 and 3.9.1). By further evaluating and analyzing the uncertainty factors, it is expected
37 to provide relevance for those scholars who are devoted to factor analysis, in order to make the
38 results closer to the observed values. In this study, a total of 12 experiments are set up to analyze
39 the effects of the uncertainties mentioned above, and the following conclusions are drawn: (1)
40 Horizontal resolution has a greater effect than vertical resolution. (2) The simulated effects of
41 temperature and wind speed in the N-S scheme are smaller than those in the PBL scheme. (3) The
42 initial and boundary conditions of different products have the most remarkable effect on relative
43 humidity, and the simulation results of ECMWF data are the best. (4) The updates with urban and
44 water bodies as the underlying surface have a more significant contribution to the meteorological
45 fields, especially on temperature. (5) For the PBL parameterization schemes, the update of the model
46 version has less impact on the simulation results, because each update has small changes and no
47 major changes overall. In general, the configuration of uncertainties needs to be considered
48 comprehensively according to what you need in order to obtain the best simulation results.

49

50 Introduction

51 The key factor for the accurate simulation of near-surface (N-S) meteorological parameters and
52 planetary boundary layer (PBL) structures is the PBL parameterization scheme. Part I has discussed
53 the impact of the PBL schemes in detail from the mechanism, and assessed the applicability of the
54 PBL schemes for different parameters (i.e., 2-m temperature, 2-m relative humidity, 10-m wind
55 speed and direction, PBL vertical structures, PBL height, turbulent diffusion coefficient) in different
56 regions (i.e., North China Plain, NCP; Yangtze River Delta, YRD; Sichuan Basin, SB; Pearl River
57 Delta, PRD and Northwest Semi-arid, NS) and seasons (i.e., January, April, July and October).
58 However, there are still many uncertainties in the model that can affect the forecasts and model
59 results. The model settings used by different scholars exhibit differences in the simulation results.
60 For example, the horizontal and vertical resolutions are essential for model settings. Horizontal

61 resolution, as a critical factor, must be considered in all models, whether they are macroscale earth
62 system models (Ma-ESMs), climate models (CMs) mesoscale weather models (Me-WMs), or
63 microscale fluid models (Mi-FMs). Constrained by computational resources, a horizontal resolution
64 of about 100~250 km is used for Ma-ESMs models (e.g., Coupled Model Intercomparison Project
65 phase 6, CMIP6 model) (D. Li et al., 2022; Taylor et al., 2012). The horizontal resolution of CMs
66 typically ranges from 50 to 25 km (e.g., Flexible Global Ocean-Atmosphere-Land System Finite-
67 Volume version 3, FGOALS-f3 model)(J. Li et al., 2021). The horizontal resolution of Me-WMs
68 (e.g., The Global/Regional Assimilation Prediction System, GRAPES model, Weather Research and
69 Forecasting, WRF model)(García-García et al., 2022; Ma et al., 2018) can be as fine as 1 km. The
70 Mi-FMs can have a horizontal resolution of less than 100 m (e.g., Large eddy simulation, LES
71 model)(Zhou et al., 2017). Studies have shown that the interaction between large- and small-scales
72 is influenced by resolution, with finer resolution allowing for better characterization of underlying
73 surface features and extreme events(Rummukainen, 2016; Singh et al., 2021), and also impacting
74 future climate predictions(Chang et al., 2020; Roberts et al., 2020; Small et al., 2014). The use of
75 PBL scheme is usually in coarse resolution models, which can lead to additional errors since these
76 schemes are developed for flat terrain conditions(Weigel et al., 2007).

77 Finer vertical resolution can better capture changes in PBL structures, which can also have an impact
78 on mass transport(Menut et al., 2013; O'Dea et al., 2017; Teixeira et al., 2016), especially on the
79 accuracy of wind resources (Tolentino et al., 2016). In addition, horizontal and vertical resolutions
80 can cause spurious gravity waves and increase model errors(Nolan and Onderlinde, 2022). Although
81 finer resolution is better, there is no doubt that it is computationally expensive. Whether the use of
82 finer resolution will bring significant improvement to the model results deserves further discussion.

83 Different PBL schemes are combined with the different N-S schemes, both of which are crucial to
84 the simulation results of the meteorological fields(Jia and Zhang, 2020). For instance, the MYJ PBL
85 scheme can only couple the Eta N-S scheme, while the BL PBL scheme can couple both the MM5
86 and the Eta N-S schemes. The N-S scheme is pivotal for mesoscale numerical simulation, especially
87 for fine numerical forecasting(Y. Li et al., 2010). Then, to figure out which scheme has a greater
88 impact on the meteorological field will help to make targeted improvements to the forecasts in the
89 future.

90 In addition, the lag of the underlying surface data can also affect the simulation results of the
91 meteorological fields, especially for large cities with relatively rapid urbanization (Qian et al., 2022).

92 In particular, different underlying surface conditions can have different albedos that affect the
93 temperature changes, which can affect the urban heat island effect from a local perspective and
94 global warming from a global perspective.(Ouyang et al., 2022; Schwaab et al., 2021; Wang and Li,
95 2021).

96 The most commonly used final (FNL) reanalysis dataset is jointly produced by the National Centers
97 for Environmental Prediction (NCEP) and the National Center for Atmospheric Research (NCAR).
98 They have adopted a global data assimilation system and a well-established database for quality
99 control and assimilation of observations from various sources (ground, ships, radio soundings, wind
100 balloons, aircraft, satellites, etc.) to obtain a complete set of reanalysis dataset. The European Center
101 for Medium-Range Weather Forecasting (ECMWF, hereafter referred to as EC) has concluded that
102 the steady progress in numerical forecasting over the last 30 years is mainly attributed to
103 improvements in the forecast models themselves, the application of more observations and the
104 development of data assimilation techniques(Magnusson and Källén, 2013). Among them, the
105 performance of the forecast model depends largely on the model resolution, the accuracy of the
106 finite difference method, and the representativeness of the physical process parameterization
107 scheme. Different initial fields also influence the model results due to different observational data,
108 quality control methods, assimilation schemes, and bias correction methods adopted for different
109 reanalysis data(Ma et al., 2021).

110 Finally, we also have to take the update of the model version into account. With model versions
111 being updated, many parameterization schemes are more or less updated(Morichetti et al., 2022).
112 However, under the circumstance that the updates are not disclosed in scientific and technical reports
113 or papers, we need to dig into them from the code itself. In reality, simulation results will be likely
114 to vary from scholar to scholar because of different model versions they choose(Jia and Zhang,
115 2020). Consequently, it is necessary to adopt a control variable approach when discussing the impact
116 of model version updates. Instead of updating all parameterization schemes, only by updating the
117 ones we are concerned with can the uncertainty arising from version updates can be quantified.

118 These aforementioned uncertainties have been studied by scholars individually, but few scholars
119 have been able to synthesize and analyze these factors. In this part (i.e., Part II), each of these
120 uncertainties will be analyzed and discussed, and the factors with more significant effects will be
121 selected for reference in that identifying which factors besides the PBL scheme are critical to the
122 simulation of meteorological fields makes all the difference.

123 2. Data and Methodology

124 2.1 Data

125 2.1.1 Reanalysis Data

126 *Final (FNL) reanalysis data.* The NCEP global FNL reanalysis data are based on the 6 h
127 temporal resolution (i.e., 00:00 (08:00), 06:00 (14:00), 12:00 (18:00), 18:00 (02:00) UTC (BJT))
128 by the Global Data Assimilation System (GDAS) with a resolution of $1^{\circ} \times 1^{\circ}$ or $0.25^{\circ} \times 0.25$
129 $^{\circ}$. This product continuously collects observational data from the Global Telecommunications
130 System (GTS) and other sources. The FNL reanalysis data are made with the same model as
131 NCEP uses in the Global Forecast System (GFS), but the FNL reanalysis data are prepared
132 about an hour or so after the GFS is initialized. The FNL reanalysis data parameters include
133 surface pressure, sea level pressure, geopotential height, temperature, sea surface temperature,
134 soil values, ice cover, relative humidity, winds, vorticity etc. The data temporal range for 1-
135 degree is from July 30, 1999 to the present (<https://rda.ucar.edu/datasets/ds083.2/>), while the
136 time range for the 0.25-degree is from July 8, 2015 to the present
137 (<https://rda.ucar.edu/datasets/ds083.3/>).

138 *The fifth generation ECMWF reanalysis (ERA5) data.* The ERA5 is the fifth generation EC
139 reanalysis of the global climate. Reanalysis combines model data with observations worldwide
140 to form a globally complete and consistent dataset. ERA5 replaces its predecessor, the ERA-
141 Interim reanalysis. ERA5 data is available from 1959 to present with a resolution of $0.25^{\circ} \times$
142 0.25° (atmosphere) and $0.5^{\circ} \times 0.5^{\circ}$ (ocean waves). The model requires 3D data and 2D data,
143 and the variables of 3D data are temperature, U and V components of wind, geopotential height,
144 relative humidity ([https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-pressure-](https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-pressure-levels?tab=overview)
145 [levels?tab=overview](https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-pressure-levels?tab=overview)). The 2D data mainly includes the parameters surface pressure, mean sea
146 level pressure, skin temperature, 2-m temperature, 2-m relative humidity, 10-m U and V
147 components of wind, soil data and soil height
148 ([https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-single-](https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-single-levels?tab=overview)
149 [levels?tab=overview](https://cds.climate.copernicus.eu/cdsapp#!/dataset/reanalysis-era5-single-levels?tab=overview)).

150 2.1.2 Underlying surface data

151 The default underlying surface data in WRF are USGS and MODIS data, where USGS has 24

152 classifications and MODIS has 20 classifications. In this study, MODIS data is selected. The
153 basic land cover is a modified International Geosphere Biosphere Programmer (IGBP), which
154 is calculated by supervised classification using MODIS Terra and Aqua reflectance data, with
155 a resolution of 500 m
156 (https://www2.mmm.ucar.edu/wrf/users/download/get_sources_wps_geog.html). The dataset
157 that comes with WRF is based on the year 2001(Bhati and Mohan, 2016). The 20 types are
158 evergreen needleleaf, evergreen broadleaf, deciduous needleleaf, deciduous broadleaf, mixed
159 forest, closed shrublands, open shrublands, woody savannas, savannas, grasslands, permanent
160 wetlands, croplands, urban and built-up, cropland mosaics, snow and ice, bare soil and rocks,
161 water bodies, wooded tundra, mixed tundra and barren tundra.

162 To consider the influence of the underlying surface data on the model results, we further select
163 the same underlying surface data as the simulation period (i.e., January 2016)
164 (<https://e4ftl01.cr.usgs.gov/MOTA/MCD12Q1.006/>). This data is MCD12Q1 version 6 data
165 product(Friedl et al., 2002), including 17 land types that cover the IGBP land cover
166 classification.

167 2.2 Description of the modelling experiments

168 The regional settings and basic settings of the model are the same as those in Part I, still for the five
169 regions, and the month is selected as the test time only for January. To evaluate the effect of these
170 uncertainties on the simulation results of the meteorological fields, a total of 12 experiments are
171 conducted, and the detailed configuration of the experiments is shown in Table 1. The effect of
172 horizontal resolution is presented by three experimental comparisons in Exp1, Exp2 and Exp3, and
173 the effect of vertical resolution by Exp3 and Exp4. The implications of the surface layer schemes
174 are analyzed by comparing three experiments in Exp5, Exp6 and Exp7. The impact of the initial
175 field and boundary conditions are compared by three experiments, i.e., Exp3, Exp8 and Exp9. The
176 influences of the underlying surface are displayed by two Exp3 and Exp10. The update of the model
177 version is compared by Exp11 and Exp12.

178 Table 1 Detail parameters setting of the 12 experiments

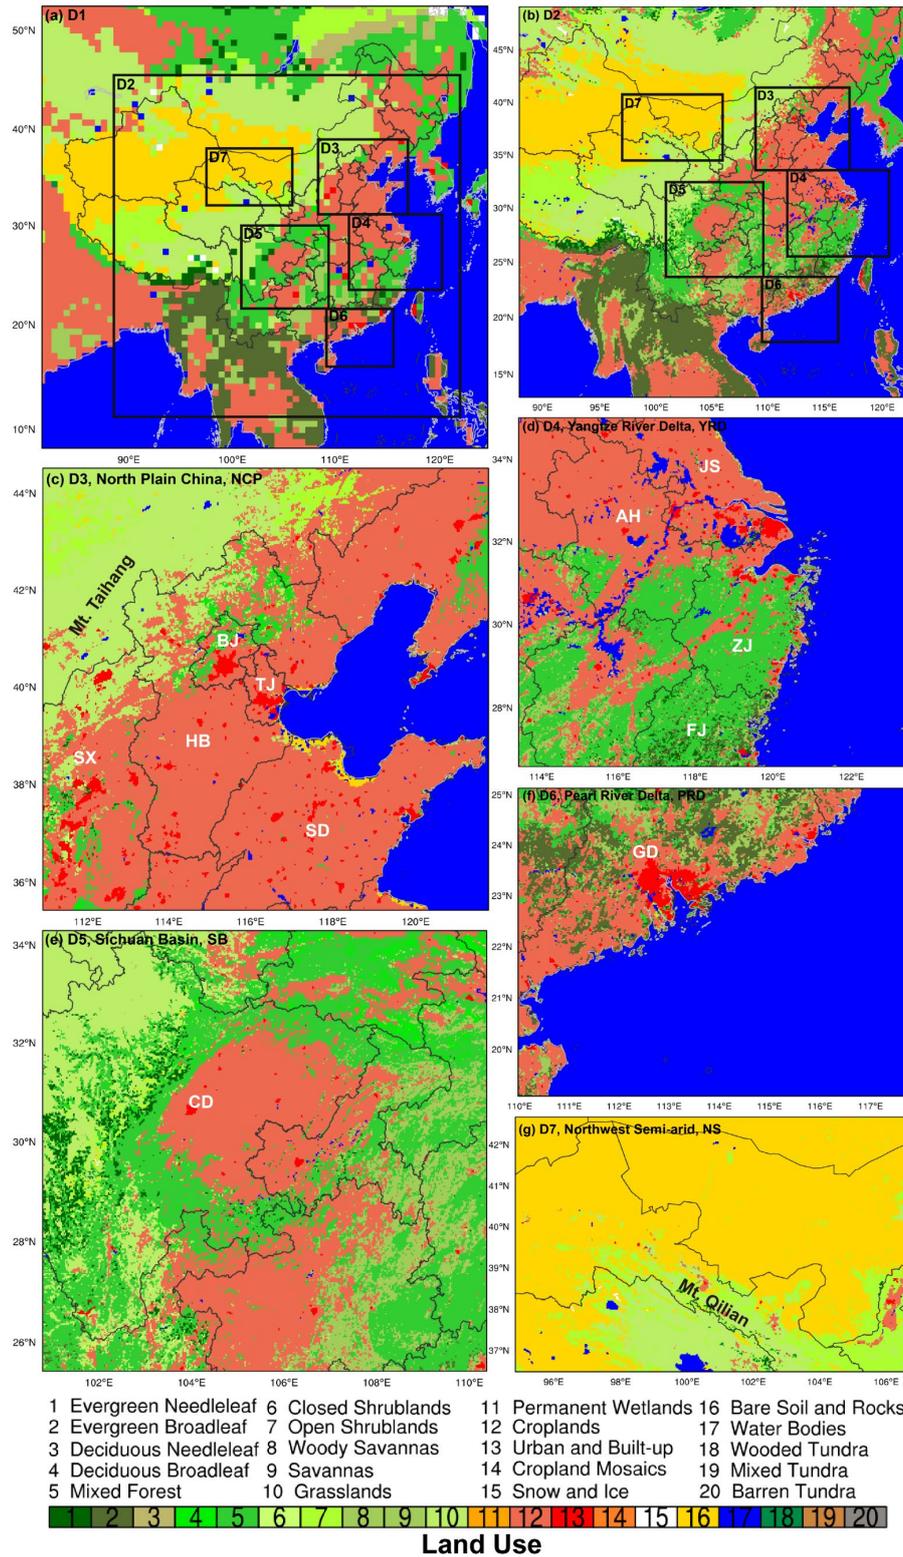

Experiments	Horizontal resolution	Vertical resolution	PBL schemes	N-S schemes	Initial field and boundary condition	Underlying surface	Version of Model
Exp1	75 km	48 levels	YSU	MM5	FNL-1 °	Modis-15s	WRF v3.9.1
Exp2	15 km	48 levels	YSU	MM5	FNL-1 °	Modis-15s	WRF v3.9.1
Exp3	3 km	48 levels	YSU	MM5	FNL-1 °	Modis-15s	WRF v3.9.1
Exp4	3 km	62 levels	YSU	MM5	FNL-1 °	Modis-15s	WRF v3.9.1
Exp5	3 km	48 levels	BL	MM5	FNL-1 °	Modis-15s	WRF v3.9.1
Exp6	3 km	48 levels	MYJ	Eta	FNL-1 °	Modis-15s	WRF v3.9.1
Exp7	3 km	48 levels	BL	Eta	FNL-1 °	Modis-15s	WRF v3.9.1
Exp8	3 km	48 levels	YSU	MM5	FNL-0.25 °	Modis-15s	WRF v3.9.1
Exp9	3 km	48 levels	YSU	MM5	EC-0.25 °	Modis-15s	WRF v3.9.1
Exp10	3 km	48 levels	YSU	MM5	FNL-1 °	Modis-15s (2017)	WRF v3.9.1
Exp11	3 km	48 levels	ACM2	MM5	FNL-1 °	Modis-15s	WRF v3.9.1
Exp12	3 km	48 levels	ACM2	MM5	FNL-1 °	Modis-15s	WRF v3.6.1⁺*

179 *WRF3.6.1⁺ refers to the migration of the ACM2 scheme from WRFv3.6.1 to WRFv3.9.1, ensuring
180 that no changes in other parameterization schemes. Bold text indicates uncertainties of primary
181 concern.

182 3 Results and discussion

183 3.1 horizontal resolution impact on 2-m temperature and 10-m wind speed

184 The underlying surface information is crucial to the simulation of near-surface meteorological
185 parameters. From the distribution of the underlying surface, the three different resolutions of the
186 model can basically capture the general information of the underlying surface (Fig. 1). The
187 resolution of 75 km is relatively coarse, so many fine features are ignored and represented uniformly
188 by a large grid (Fig. 1a). The resolution of 15 km is very significantly different compared to 75 km
189 (Fig. 1b), and many fine characteristics (e.g., lakes, cities, etc.) are represented, very close to the
190 features of 3 km.

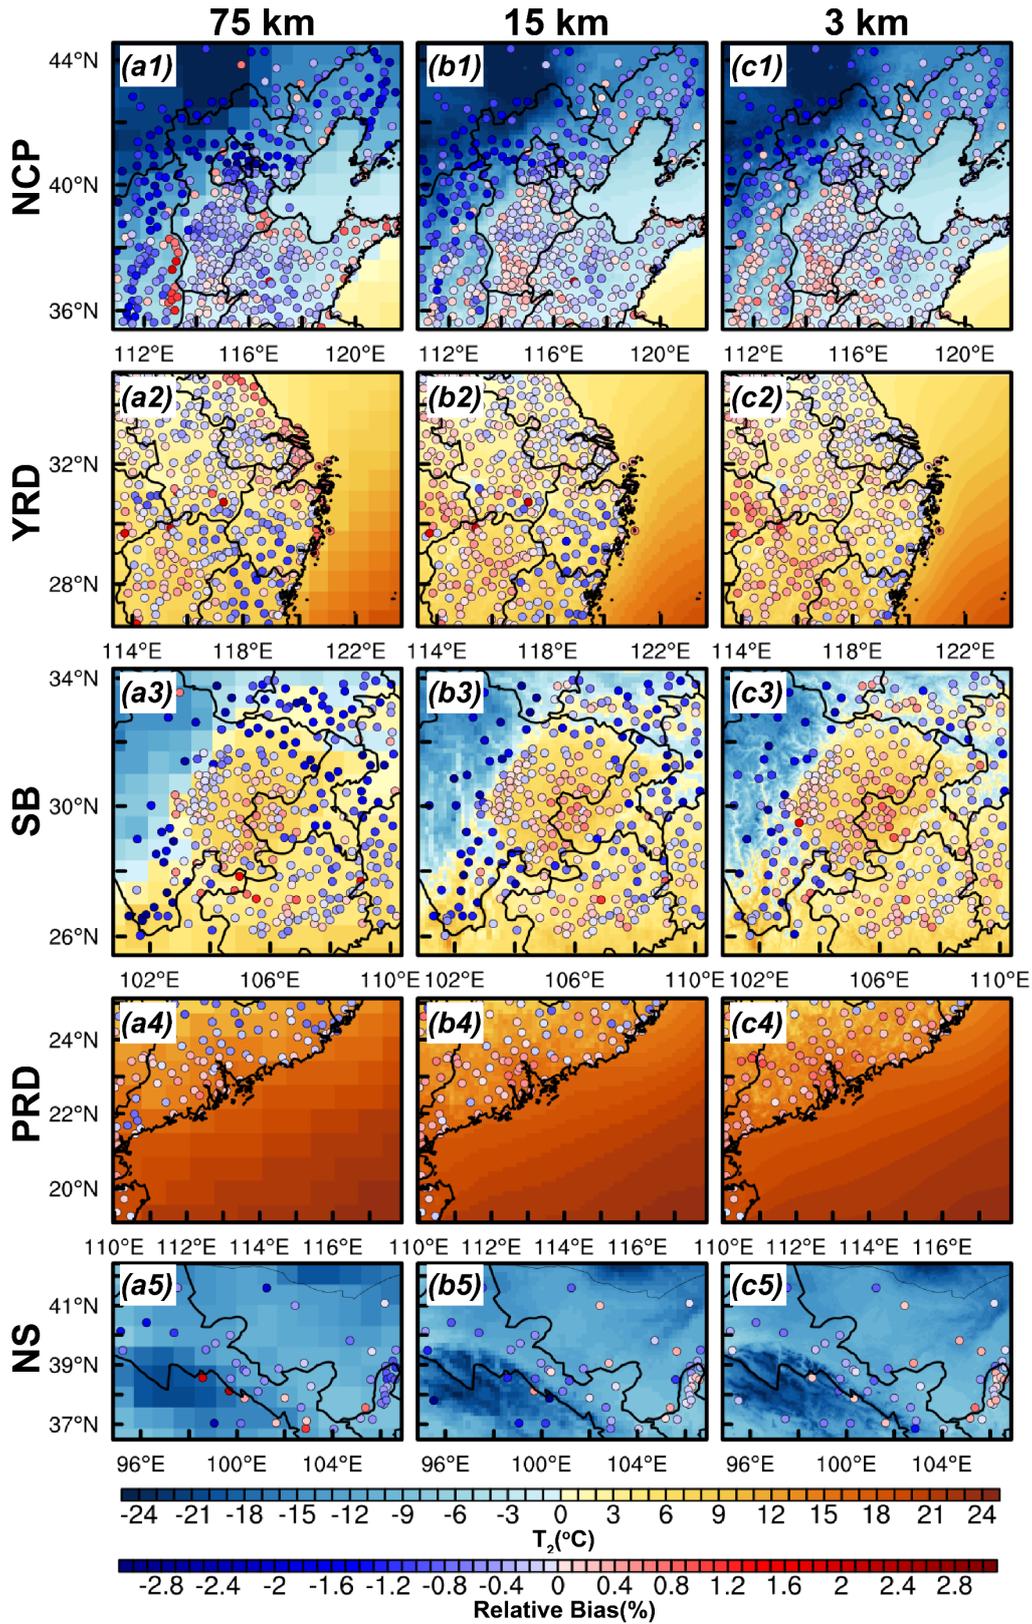

191
192
193
194
195
196

Figure 1. (a-g) Map of land use type in the seven nested model domains. The abbreviations BJ, TJ, HB, SX, SD, JS, ZJ, AH, FJ, CD, GD, Mt. Taihang and Mt. Qilian are denoted as Beijing Shi, Tianjin Shi, Hebei province, Shanxi province, Shandong province, Jiangsu province, Zhejiang province, Anhui province, Fujian province, Chengdu Shi, Guangdong province, Taihang mountains and Qilian mountains in figure c-g, respectively.

197 Further comparative analysis of temperature and wind speed in five regions at these three resolutions
198 have been performed. In terms of regional distribution, all three experiments can simulate high and
199 low value areas of 2-m temperature, but there are differences in the degree of overestimation and
200 underestimation (Fig. 2). In the NCP region, the three experiments underestimate the temperature
201 over a similar range of regions, especially in the northwest (Fig. 2a1-c1). Experiment 1 differs more
202 sharply from the other two experiments in areas with more marked underlying surface variability
203 such as in the complex mountainous areas (i.e., Taihang mountains, Mt. Taihang) in the northwest,
204 the underestimation of Exp1 is more significant, but at the sea-land interface, the overestimation of
205 Exp1 is more pronounced (Fig. 2a1), because the grid resolution is too low. The number (N) of
206 stations overestimated by the three experiments is 96, 128 and 172, and the relative bias (RB) are
207 0.38%, 0.19% and 0.18%, respectively. Although the number of stations overestimated by Exp1 is
208 small, there are more extreme values, so the deviation is larger. Correspondingly, the higher degree
209 of underestimation (-0.89%) in Exp1 derives from more minimal values and stations (N=397) as
210 well. For the YRD region, obviously, Fig. 2a2-c2 note that the RB of the stations vary greatly with
211 different horizontal resolutions, especially for the northeastern coastal of YRD region (i.e., northeast
212 Jiangsu (JS) province) from overestimation (Fig. 2a2) to underestimation (Fig. 2c2), and the degree
213 of underestimation gradually decreases in the southeast of YRD (i.e., Zhejiang (ZJ) and Fujian (FJ)
214 provinces). In the SB region, it is clear that Exp1 underestimates the 2-m temperature more
215 significantly (RB=-1.11%, N=245), with fewer stations in the fig. 2a3, followed by Exp2 (RB=-
216 1.03%, N=208), and to a lesser extent by Exp3 (RB=-0.69%, N=152). The PRD region behaves
217 differently from other regions, with the simulation results of Exp1 showing an underestimation
218 (RB=-0.11%), while Exp2 (RB=0.13%) and Exp3 (RB=0.35%) an overestimation (Fig. 2a4-c4).
219 The variation of underlying surface between grids in the PRD region is more complex in comparison
220 with other regions (Fig. 1). This does not indicate that the simulation results are better when the grid
221 horizontal resolution is lower, because the scheme itself still has errors in the simulation. It only
222 reveals that the simulation results of Exp1 perform better statistically in the current model
223 configuration for this region. The number of stations in Exp1 in the NS region is much less than the
224 other two experiments, which means that the relative bias of Exp1 is more than $\pm 3\%$ and the
225 deviation is greater, for the area along the Qilian mountains (Mt. Qilian) (Fig. 2a5-c5) in particular.
226 The results of wind speed are different from those of temperature, and the difference between the
227 three experiments is not as obvious as that of temperature (Fig. 3). The three experiments

228 overestimate the wind speed to varying degrees, however, more stations underestimate wind speed
229 in the Exp1, especially in the NCP ($N_{Exp1}=34$, $N_{Exp2}=21$, $N_{Exp3}=19$) and SB region ($N_{Exp1}=29$,
230 $N_{Exp2}=18$, $N_{Exp3}=7$) (Fig. 3a3). As the grid resolution is too coarse in the Exp1, the wind speed is
231 underestimated at some stations due to the complex terrain in the NCP and SB regions (Fig. 3a1,
232 a3).

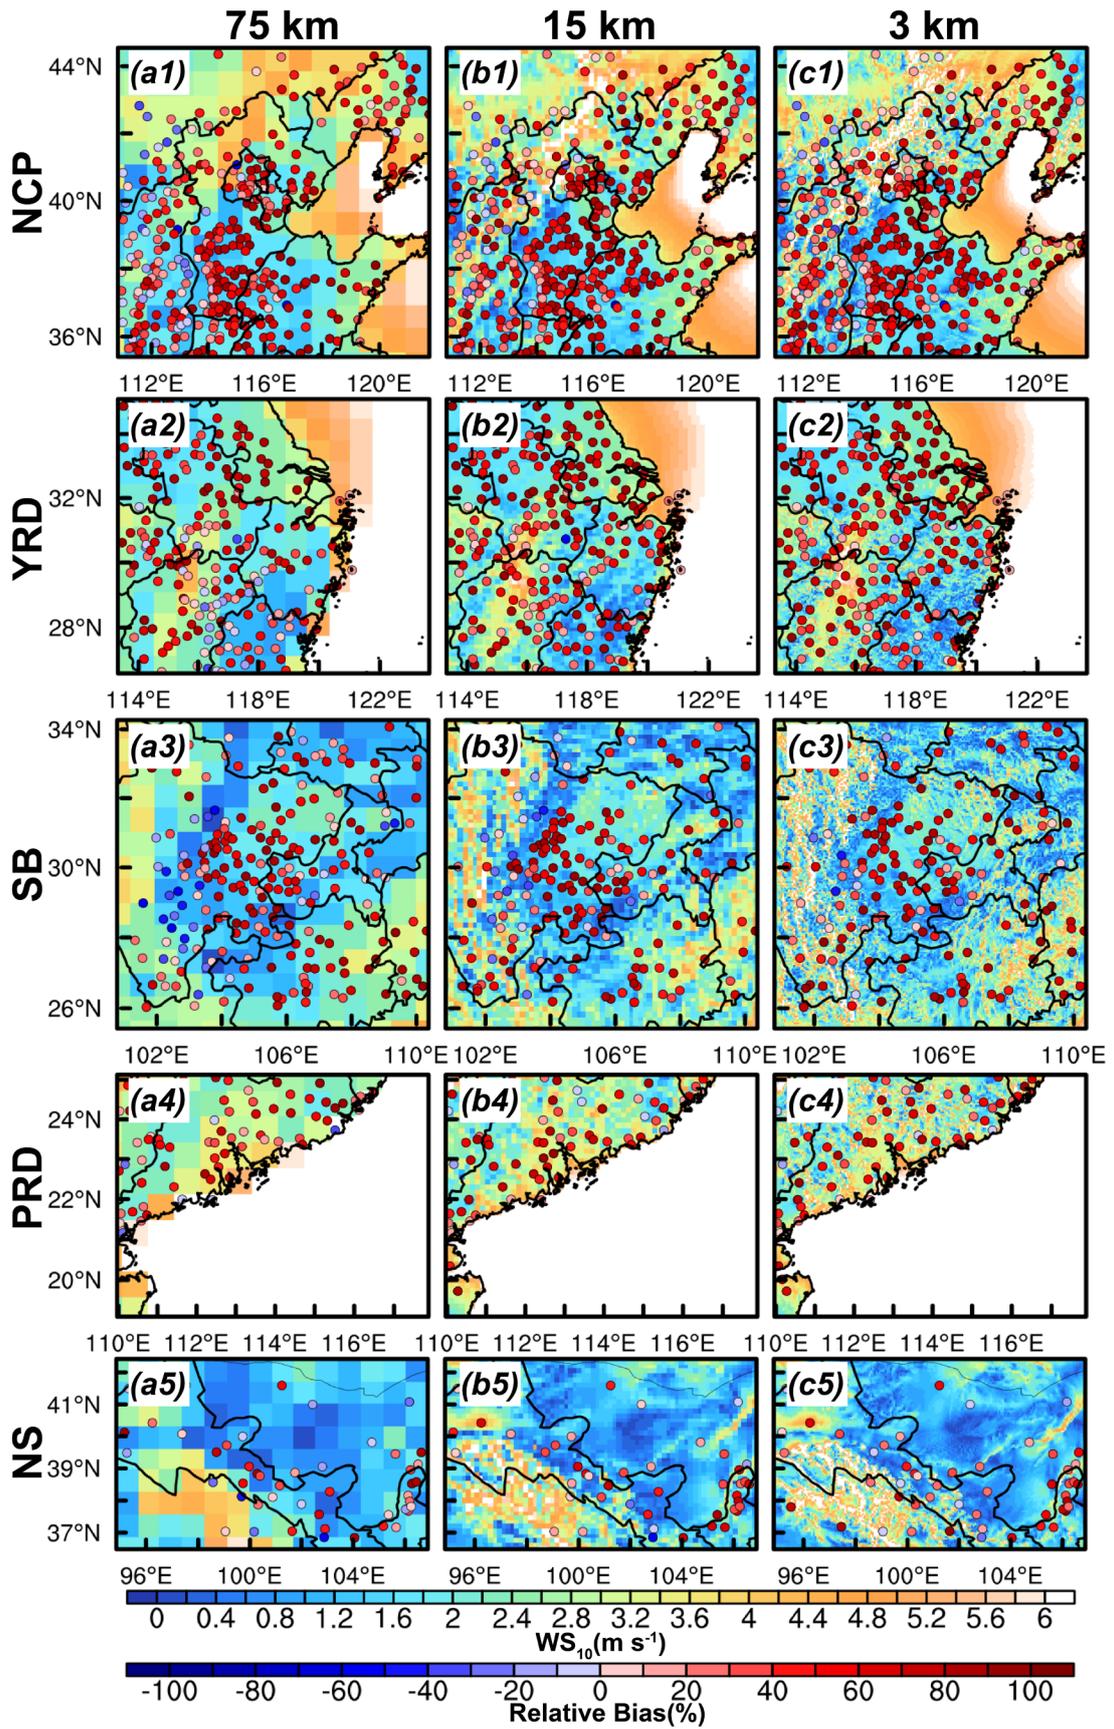

233

234 Figure 2. Regional distribution of 2-m temperature simulated by the (a) domain 1 (75 km), (b)

235 domain 2 (15 km) and (c) domain 3 (3 km) for five regions in January, and distribution of relative

236 bias between simulations and observations is denoted by scatters.

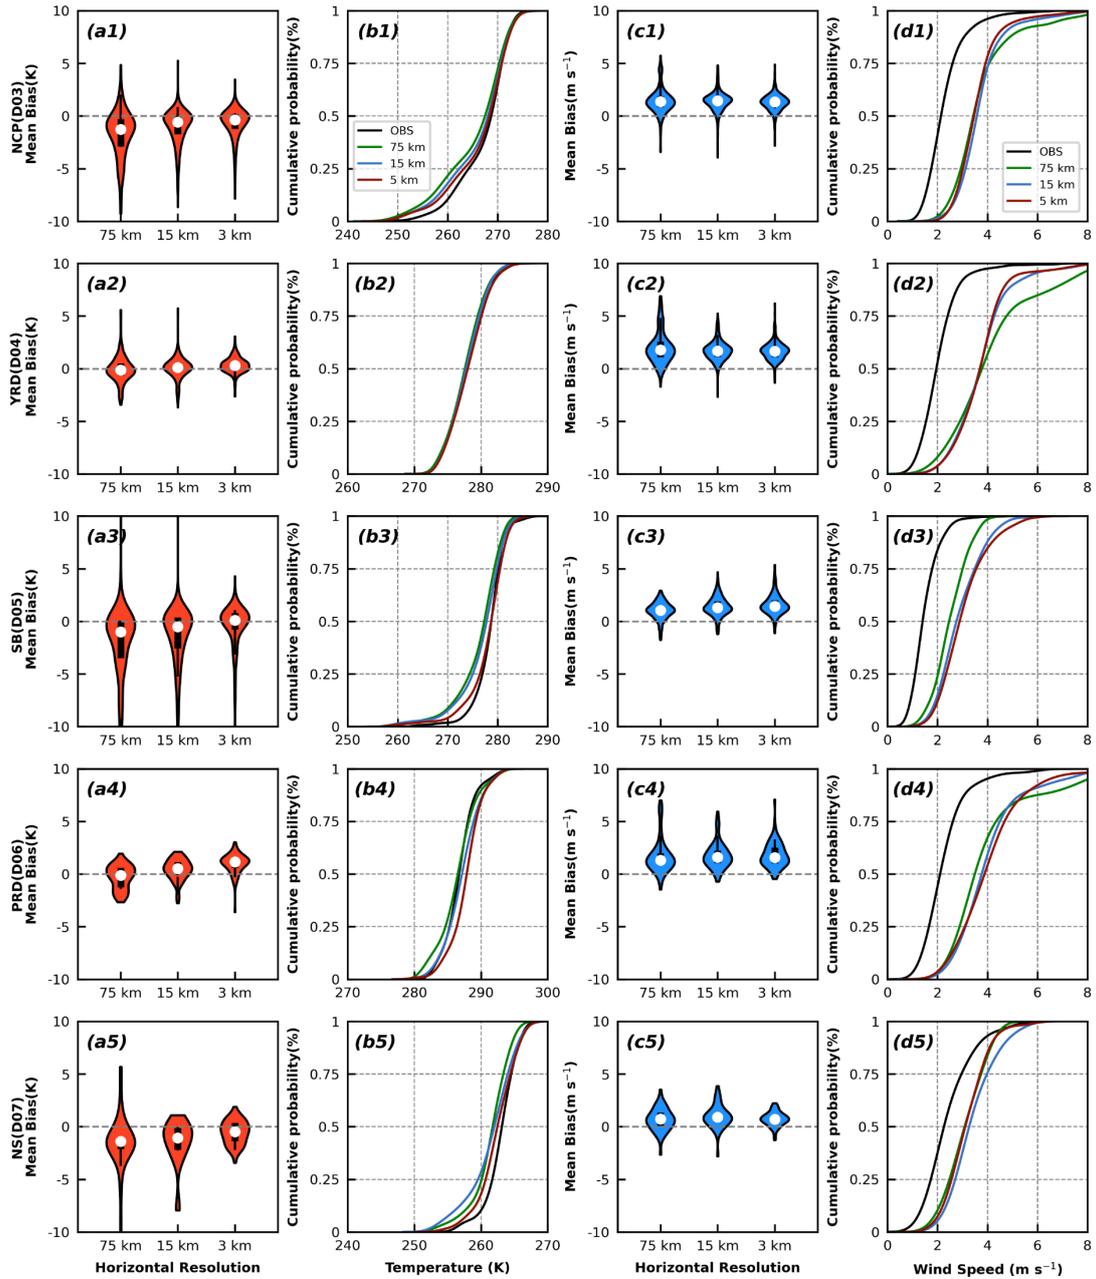

237 It can also be seen from figure 4 that the three experiments have a large difference in temperature
238 simulation, and the underestimate in Exp1 is more significant (Fig. 4a1-a5). However, in the PRD
239 region, the average value of the mean bias is closer to 0 on account of the offsetting positive and
240 negative deviations. For the distribution range of the mean bias, it has been found that the
241 distribution of the Exp1 is closer to 0 (Fig. 4a4). In terms of the cumulative probability distribution,
242 the simulations differ for different temperature segments in the NCP, SB, and NS regions. For the
243 NCP region, the temperature below 270 K is better simulated in Exp3, the temperature threshold in
244 the SB region is about 280 K, and the threshold is about 265 K in the NS region (Fig. 4b1, b3, b5).
245 In the YRD region, the simulations of all three experiments are almost the same for any segmented
246 temperature (Fig. 4b2). In addition, the PRD region is special, with temperature below about 285 K,
247 and the Exp2 simulates better (Fig. 4b4). It is worth noting that, regardless of the region, one thing
248 in common is that the temperature of the three experiments simulations gets closer and closer as the
249 temperature increases. While the difference of wind speed between the three experiments is not
250 obvious (Fig. 4c1-c5). The average value of the mean bias in Exp1 is closer to 0, mainly attributable
251 to that there are more stations with negative mean bias to offset. Wind speed and temperature behave
252 differently in regard of cumulative probability distributions, with increasing differences in simulated
253 wind speeds for the three experiments as wind speed increases (Fig. 4d1-d5). The wind speed
254 simulated in Exp1 is low, leading to a better performance in Exp1 for small wind speed (Fig. 4d1-
255 d5).

256

257

Figure 3. Similar as figure 2, but for 10-m wind speed.

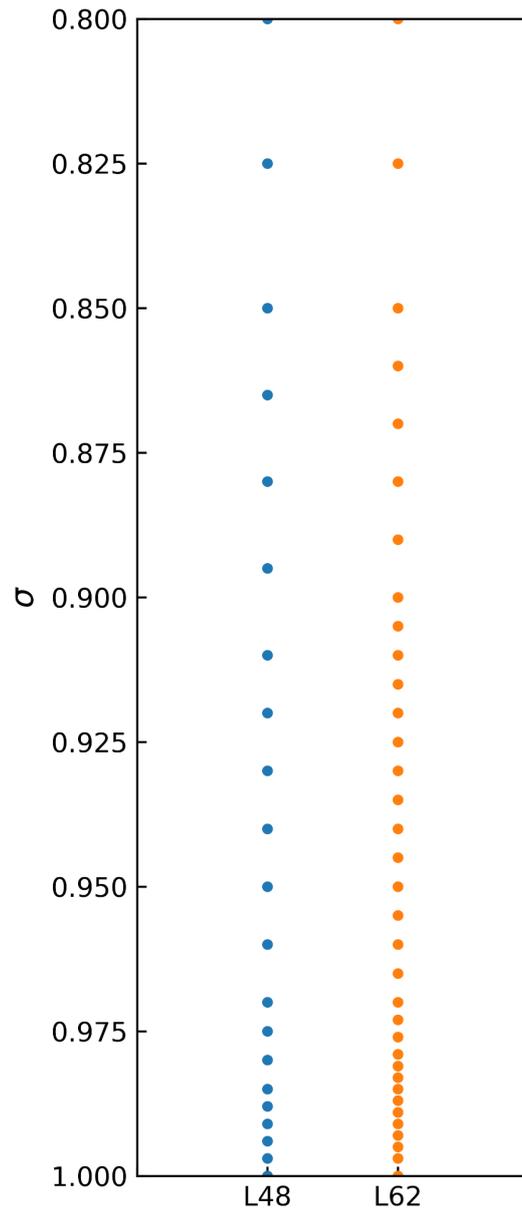

258
 259 **Figure 4.** Violin-plots of mean bias of observed and simulated (a1-a5) 2-m temperature and (c1-c5)
 260 10-m wind speed at different horizontal resolution (i.e., 75 km, 15 km, 3 km), cumulative
 261 probability of observed and simulated (b1-b5) 2-m temperature and (d1-d5) 10-m wind speed at
 262 different horizontal resolution (i.e., 75 km, 15 km, 3 km) for five regions.

263 **3.2 vertical resolution impact on PBL structures**

264 Based on Exp3, the vertical resolution has been further encrypted from 21 to 35 levels below 2 km,
 265 i.e., the total number of vertical levels is increased from 48 to 62 levels (Fig. 5). The temperature
 266 and wind fields of the two experiments (Exp3 and Exp4) simulations are compared for the four

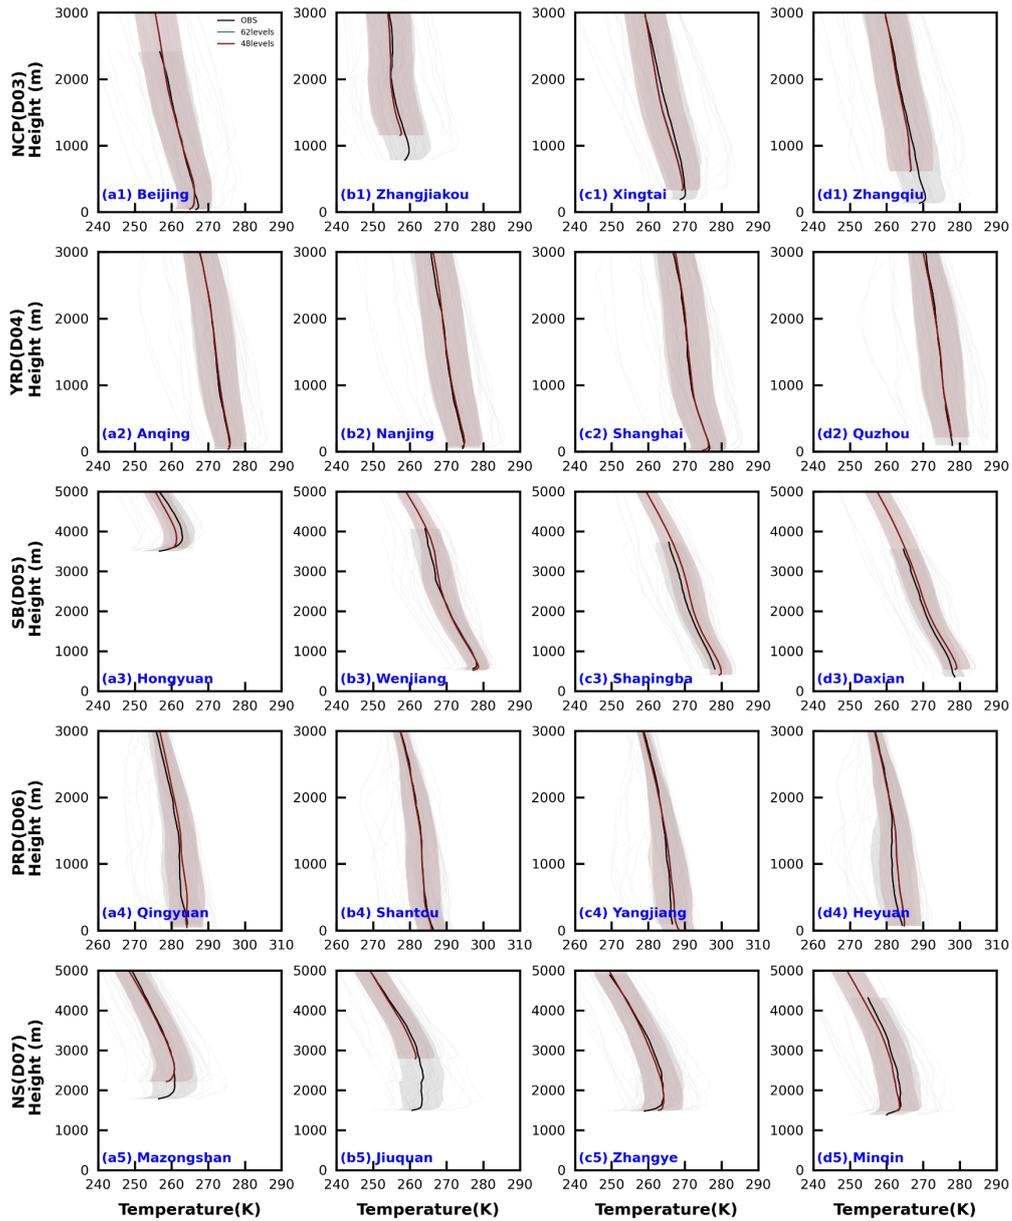

267 sounding stations selected for each region in Part I (NCP: Beijing, Zhangjiakou, Xingtai and
268 Zhangqiu; YRD: Anqing, Nanjing, Shanghai and Quzhou; SB: Hongyuan, Wenjiang, Shapingba and
269 Daxian; PRD: Qingyuan, Shantou, Yangjiang and Heyuan; NS: Mazongshan, Jiuquan, Zhangye and
270 Minqin). As can be seen from figure 6, the re-encryption of the vertical resolution has no effect on
271 the simulation of the temperature, regardless of the region. The simulation results of the two
272 experiments almost overlap in the vertical direction, implying that the vertical structure of 48 levels
273 is sufficient. On the contrary, the encryption of vertical resolution affects the simulation results of
274 wind speed to a certain extent, but the effect is marginal, especially for high altitude regions like SB
275 and NS (Fig. 7). For the YRD and PRD regions, the wind speed simulated in Exp4 is less than that
276 of Exp3 below 1000 m, with a difference of less than 1 m s^{-1} . However, the encryption of the vertical
277 resolution causes an increase in memory, which would add about 5 GB of memory for a region of
278 1-day results, and the 150 GB for a month. Therefore, the improvement in wind speed in some areas,
279 due to the increase in vertical resolution, is not worth the cost of increased memory, as the
280 improvement is simply too insignificant.

281

282

Figure 5. Vertical levels distribution for the two experiments of σ below 2 km in the model.

283

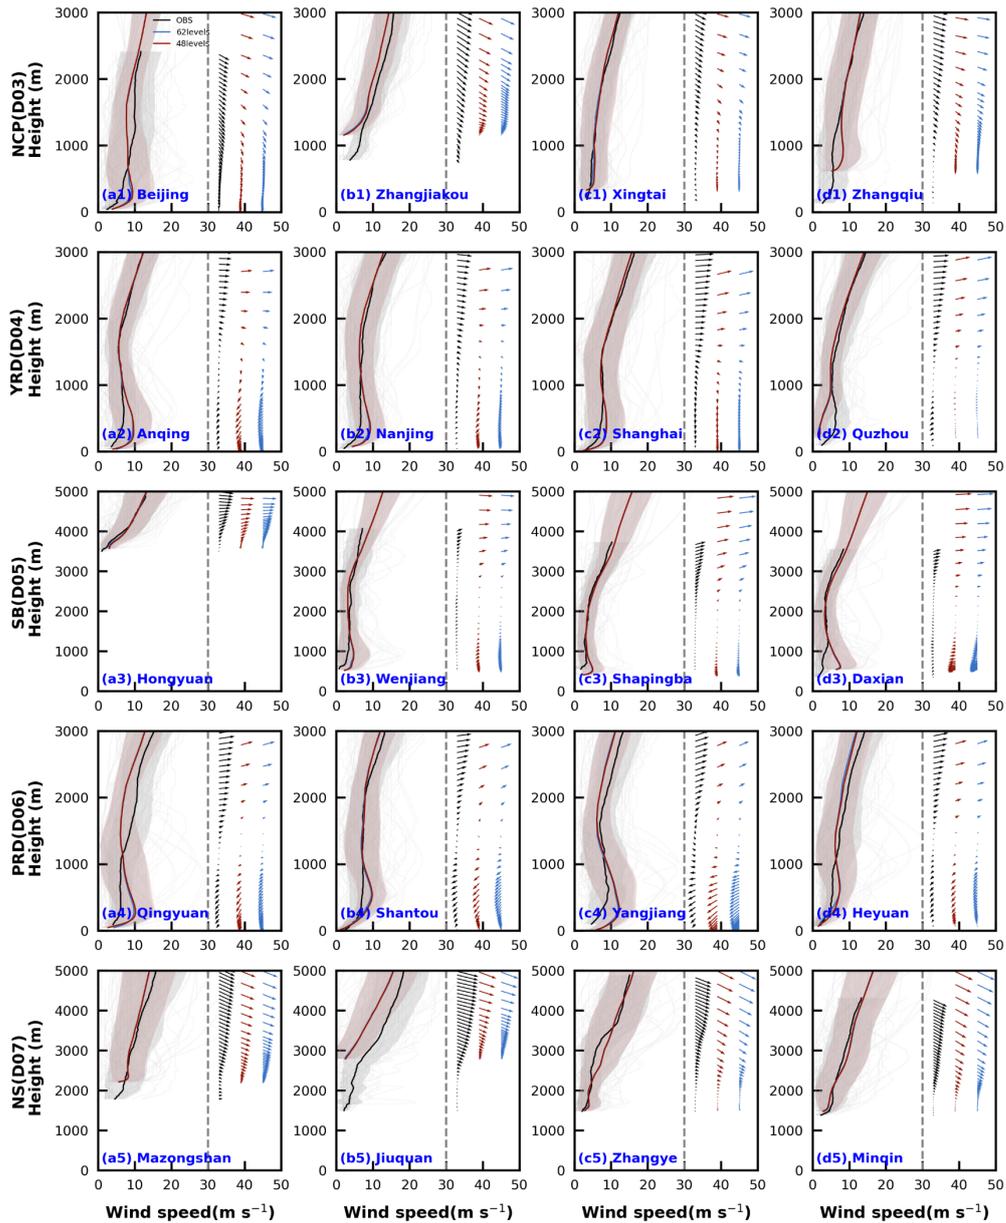

284

285

286

287

Figure 6. Average vertical profiles of observed and simulated temperature at 08:00 and 20:00 BJT at four sounding stations for each region in January. The unobtrusive gray lines indicate the simulated lines for all time periods, and the lines with shading indicate the average values and shaded areas show the uncertainty range (the mean ± 1 standard deviation).

288

289 **Figure 7. Similar as figure 6, but for wind speed and direction.**

290

It is not necessary to set the vertical resolution much finer compared to the horizontal resolution,

291

and in this experiment, 48 levels are fully sufficient to reproduce the vertical structure of the PBL.

292

3.3 near-surface (N-S) scheme impact on PBL structures

293

For the impact of the N-S scheme, this section focuses on the changes in the N-S meteorological

294

parameters.

295

The N-S and PBL schemes are fixed pairings, and three experiments (i.e., Exp5, Exp6 and Exp7)

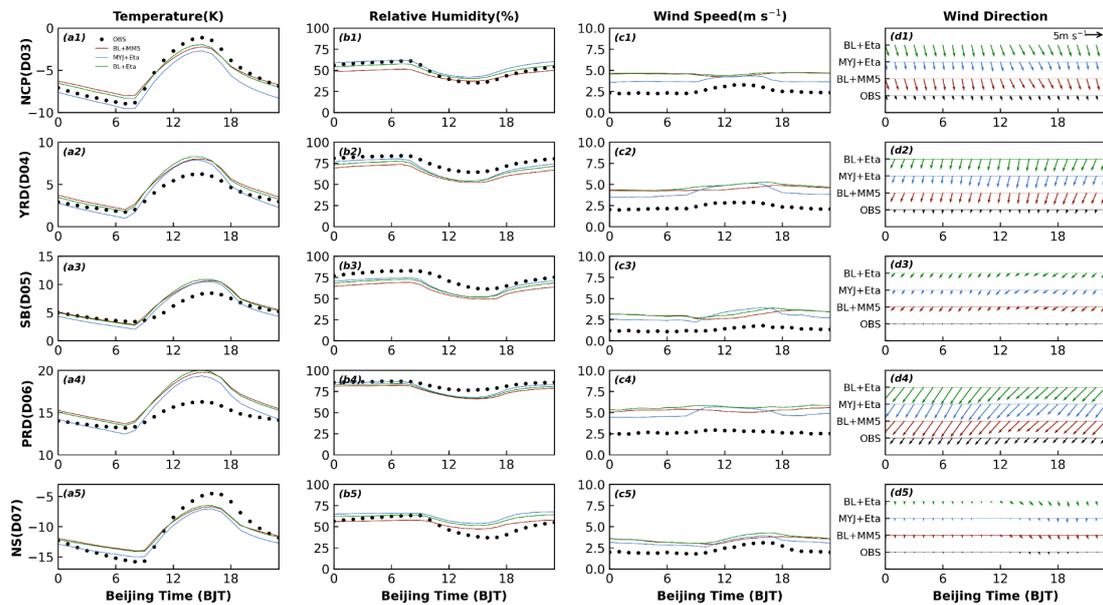

296

are done by this study to distinguish the extent to which the N-S and PBL schemes affect the N-S

297

meteorological parameters (2-m temperature, 2-m relative humidity, 10-m wind speed and direction).

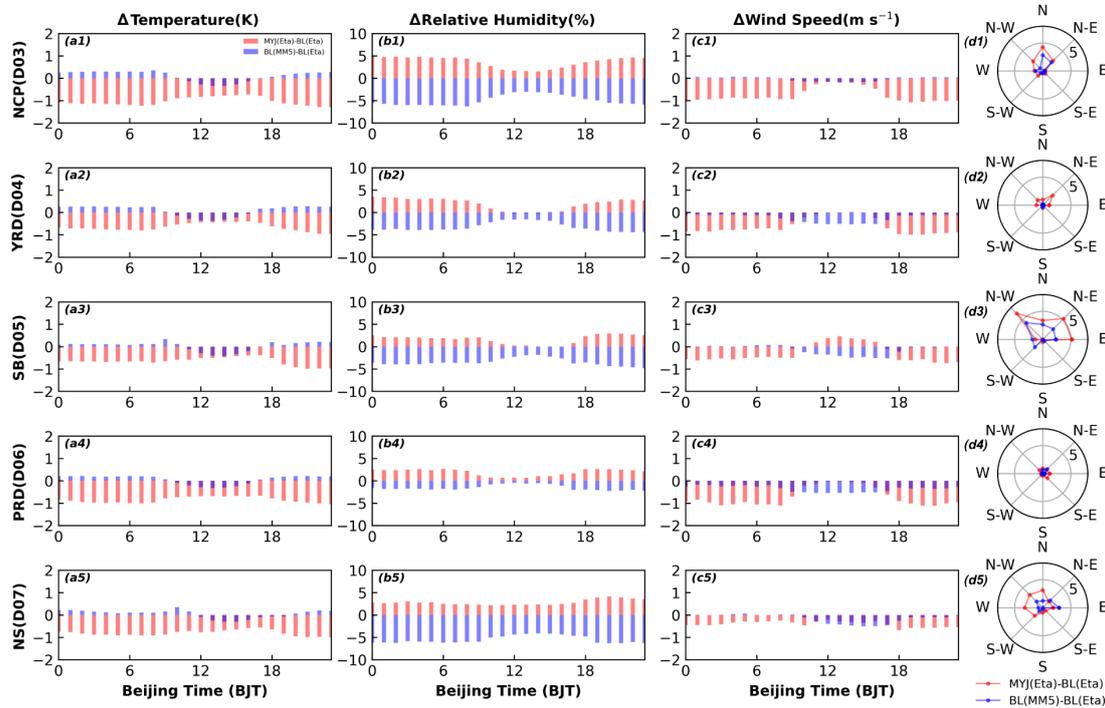

298 In terms of daily variation, the variation of temperature in the five regions is consistent, with similar
 299 simulated results in Exp5 (BL+MM5) and Exp7 (BL+Eta), and two experiments have notable
 300 differences from Exp6 (MYJ+Eta) (Fig. 8a1-a5). However, the relative humidity and temperature
 301 are different, and the results of Exp5 and Exp7 are not close to each other (Fig. 8b1-b5). From the
 302 results of wind speed, it is similar to the results of temperature, and the results of Exp5 and Exp7
 303 are much closer, as is the wind direction (Fig. 8c1-d5). Furthermore, the three schemes are made
 304 differential to quantify the impact of the PBL scheme and N-S scheme. Exp6-Exp7 note the impact
 305 of the PBL scheme, and Exp5-Exp7 illustrate the effect of the N-S scheme.

306
 307 **Figure 8. Time series of diurnal variation of (a1-a5) 2-m temperature, (b1-b5) 2-m relative**
 308 **humidity, (c1-c5) 10-m wind speed and (d1-d5) 10-m wind direction for five regions in January.**

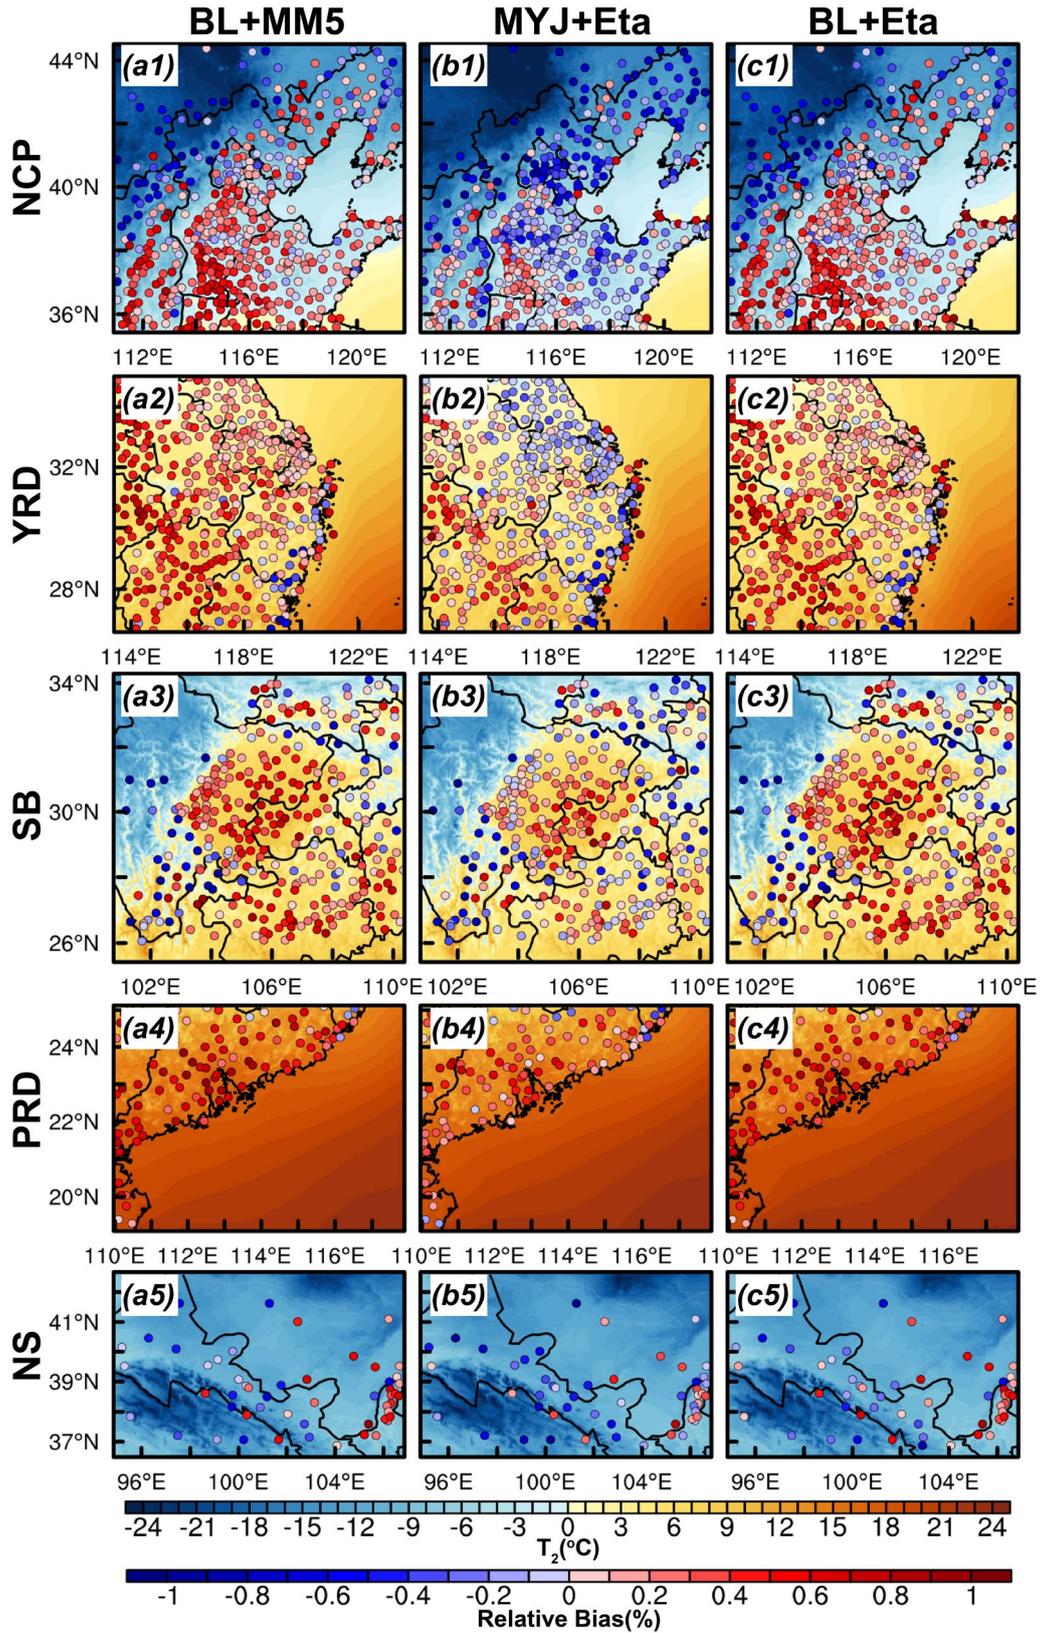

309 As can be seen from fig. 9a1-a5, the influence of the PBL scheme is greater compared to the N-S
 310 scheme in five regions. The difference in temperature simulated by different PBL schemes is about
 311 1 K, while the difference for N-S schemes is just less than 0.5 K. In figure 9b1-b5, as in figure 8,
 312 the results for relative humidity differ from those for temperature. The PBL scheme does not affect
 313 the relative humidity to the same extent as the N-S scheme, and it is also less than the N-S scheme.
 314 Particularly in the NCP, SB, and NS regions, the impact of the PBL scheme is much smaller than
 315 that of the N-S scheme (Fig. 9b1, b3, b5). Regardless of the PBL scheme and N-S scheme, the effect
 316 is greater at night than during the day. The findings for wind speed and temperature are more similar,
 317 with the PBL scheme having a remarkably greater impact than the N-S scheme (Fig. 9c1-c5). Except
 318 for the daytime in both YRD and PRD regions, the N-S scheme has a slightly greater effect on wind

319 speed than the PBL scheme (Fig. 9c2, c4). The wind direction is divided into a total of eight
 320 directions (N, N-E, E, S-E, S, S-W, W, N-W), and the influence of the PBL scheme is larger as to
 321 the percentage frequency of each direction (Fig. 9 d1-d5).

322
 323 **Figure 9. Time series of diurnal variation of the effects of PBL scheme and N-S scheme on (a1-a5)**
 324 **2-m temperature, (b1-b5) 2-m relative humidity, (c1-c5) 10-m wind speed and (d1-d5) 10-m wind**
 325 **direction for five regions in January.**

326 As for the regional distribution of temperatures, the distribution of Exp5 and Exp7 is more similar,
 327 without regard to the region, and it differs considerably from that of Exp6 (Fig. 10). Therefore, for
 328 temperature, the effect of the PBL scheme is more important. For wind speed, Exp7 simulates the
 329 largest wind speed, followed by Exp5, and Exp6 has the smallest wind speed, noting that the PBL
 330 scheme has a larger degree of influence than the N-S scheme (Fig. 11).

331

332

Figure 10. Regional distribution of 2-m temperature simulated by the (a) BL+MM5, (b) MYJ+Eta

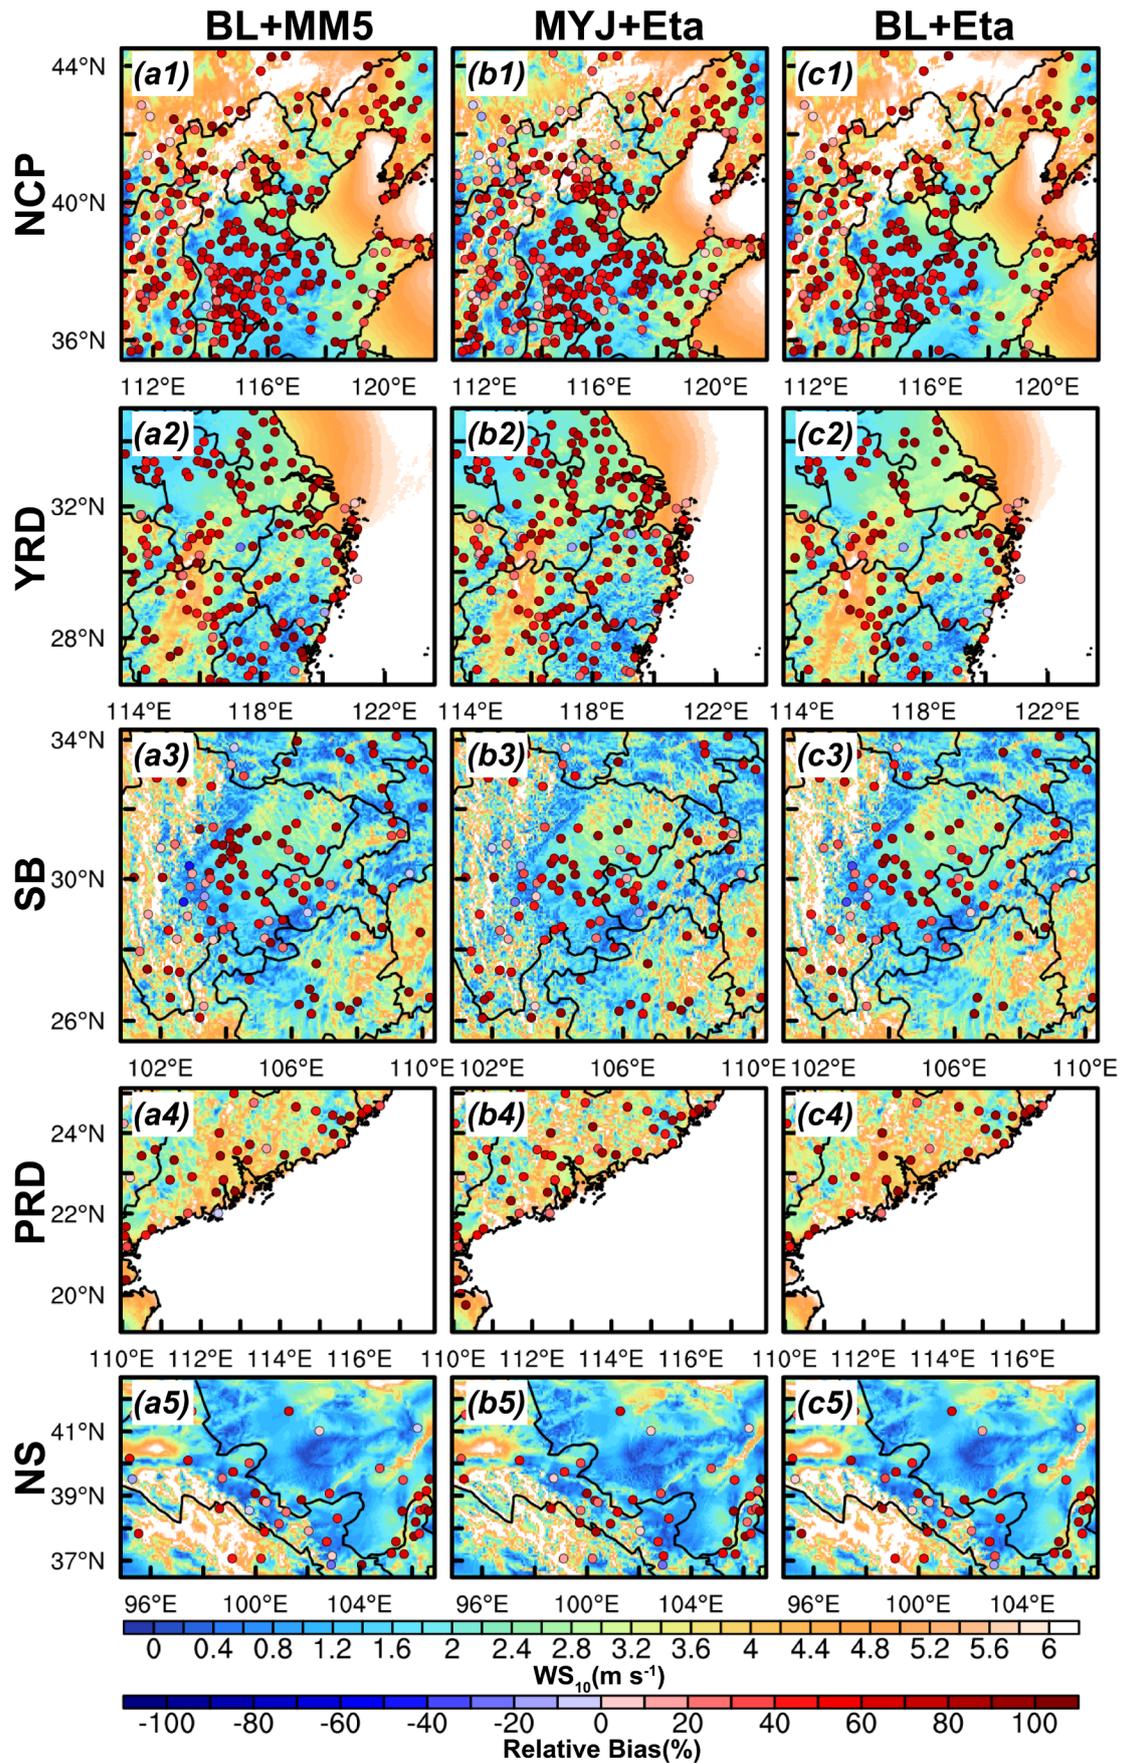

333

and (c) BL+Eta for five regions in January, and distribution of relative bias between simulations

334

and observations is denoted by scatters.

335 In general, for temperature, the choice of PBL scheme is of much more importance. For relative
336 humidity, the PBL and N-S schemes are equally important, except for the NCP, SB and NS regions,
337 where the choice of the N-S scheme is more principal. For wind speed and direction, the choice of
338 PBL scheme is more critical, and the simulation of different PBL schemes leads to more differences
339 in the results.

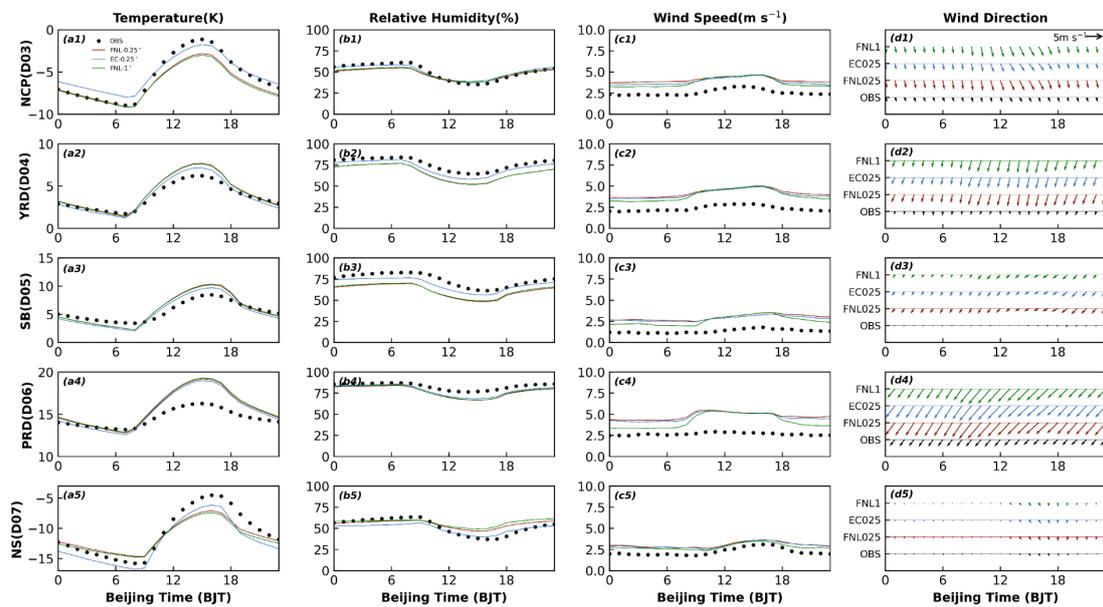

340
341

Figure 11. Similar as figure 10, but for 10-m wind speed.

342 **3.4 effect of initial and boundary conditions on meteorological parameters**

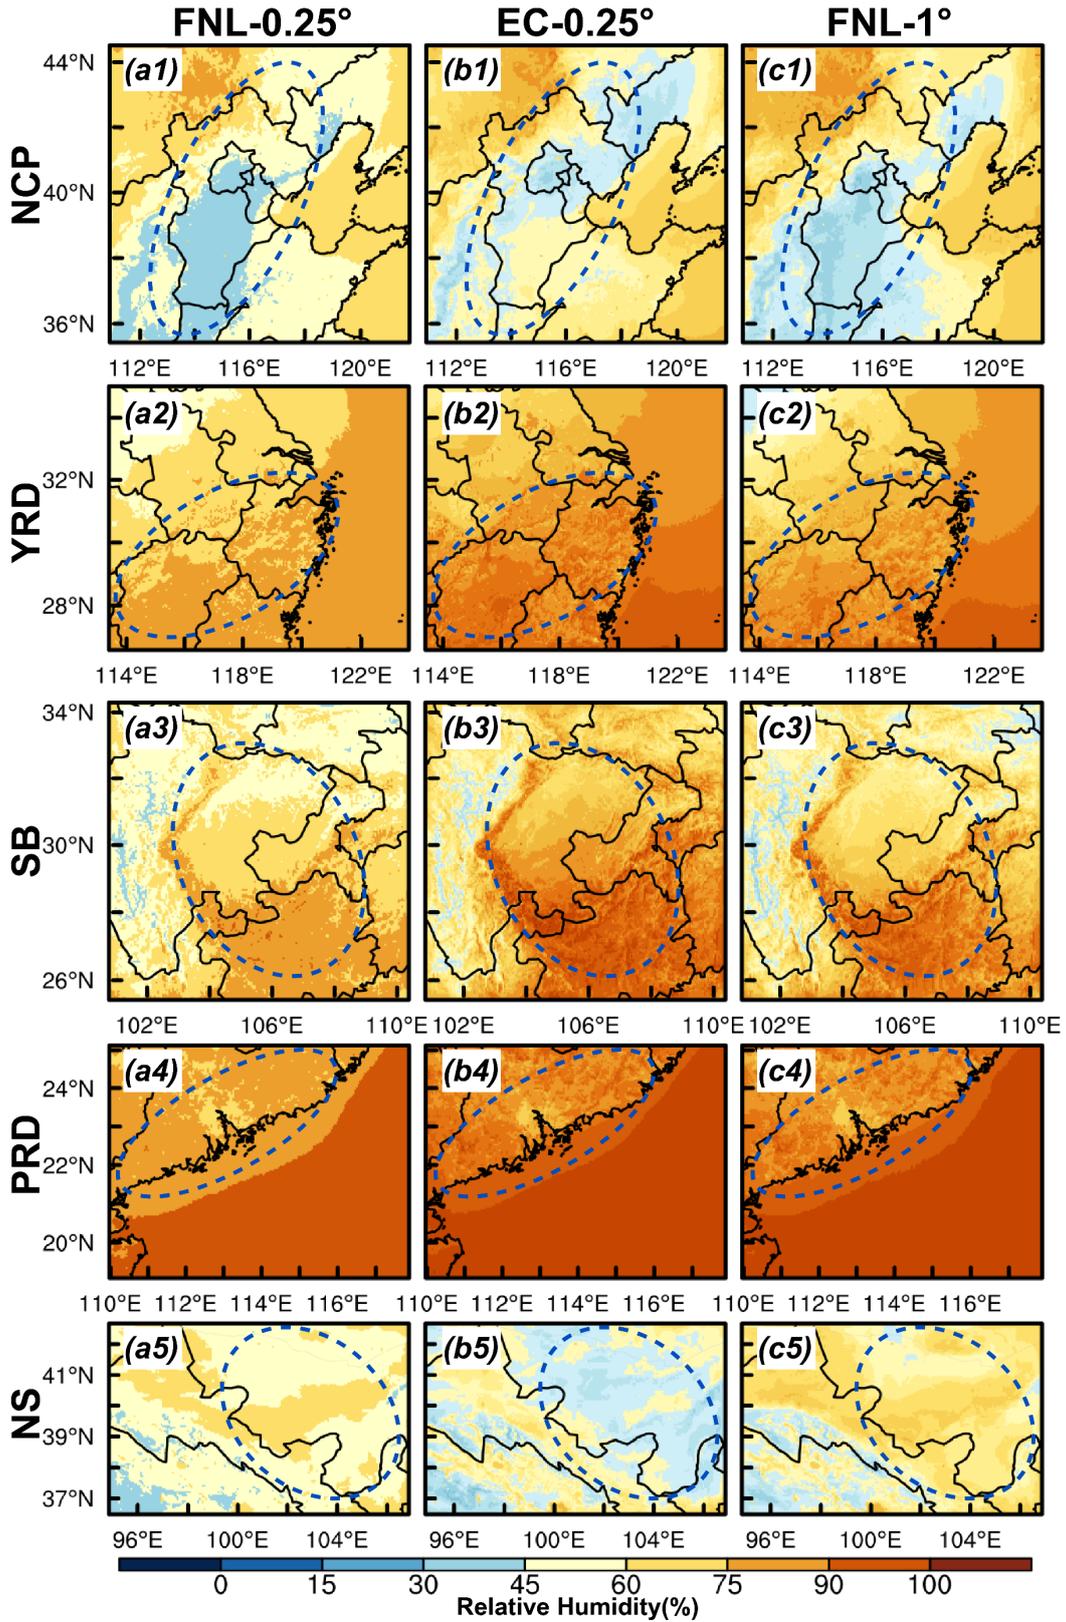

343 In this subsection, the same initial field and boundary conditions at different resolutions (i.e., FNL–
 344 1° and FNL–0.25°) and different initial field and boundary conditions at the same resolution (i.e.,
 345 FNL–0.25° and EC–0.25°) are chosen to explore the effects of the initial field and boundary
 346 conditions on the meteorological field simulation. Figure 12 shows the daily variation series of 2-m
 347 temperature, 2-m relative humidity and 10-m wind speed and direction. Also, figure 12 notes that
 348 for temperature and relative humidity, the effect of data with different resolutions of the same initial
 349 field on the results is small, but the effect of data with different initial fields of the same resolution
 350 is profound. For the five regions, the EC data better simulate the temperature than the FNL data
 351 during the day, while at night, the difference between the two types of data simulating the
 352 temperature becomes less than during the day, except for the NCP and NS regions (where the
 353 temperature difference is larger for both day and night) (Fig. 12 a1-a5). For relative humidity, the
 354 EC data are simulated better than the FNL data regardless of the region, playing a key role in
 355 improving the relative humidity results of the model (Fig. 12 b1-b5). Overall, the increase in
 356 resolution of the initial field data from 1° to 0.25° has less effect on the simulation of temperature
 357 and relative humidity, while there is a striking difference between the different initial field data.

358
 359 **Figure 12. Similar as figure 8, but for different initial and boundary conditions.**

360 The results for wind speed differ from the first two parameters in that there is almost no difference
 361 between the three experiments for wind speed simulations during the day (Fig. 12 c1-c5). However,

362 different initial field data at the same resolution have very little effect on the wind speed, but the
363 same initial field data at different resolutions have a significant effect on the wind speed, especially
364 at night (Fig. 12c1-c5). All data have a negligible effect on the wind direction (Fig. 12 d1-d5).
365 The EC data have improved the results of relative humidity for all regions as mentioned earlier (Fig.
366 12 b1-b5). In terms of regional distribution, the regional distribution of FNL data is similar in shape
367 for different resolutions (Fig. 13 a, c). However, the relative humidity distribution simulated by EC
368 data and FNL data is drastically different (Fig. 13). It is worth noting that the relative humidity of
369 the EC data is the highest in the four regions except for the NS region in which the relative humidity
370 is the lowest (Fig. 13 b1-b5).

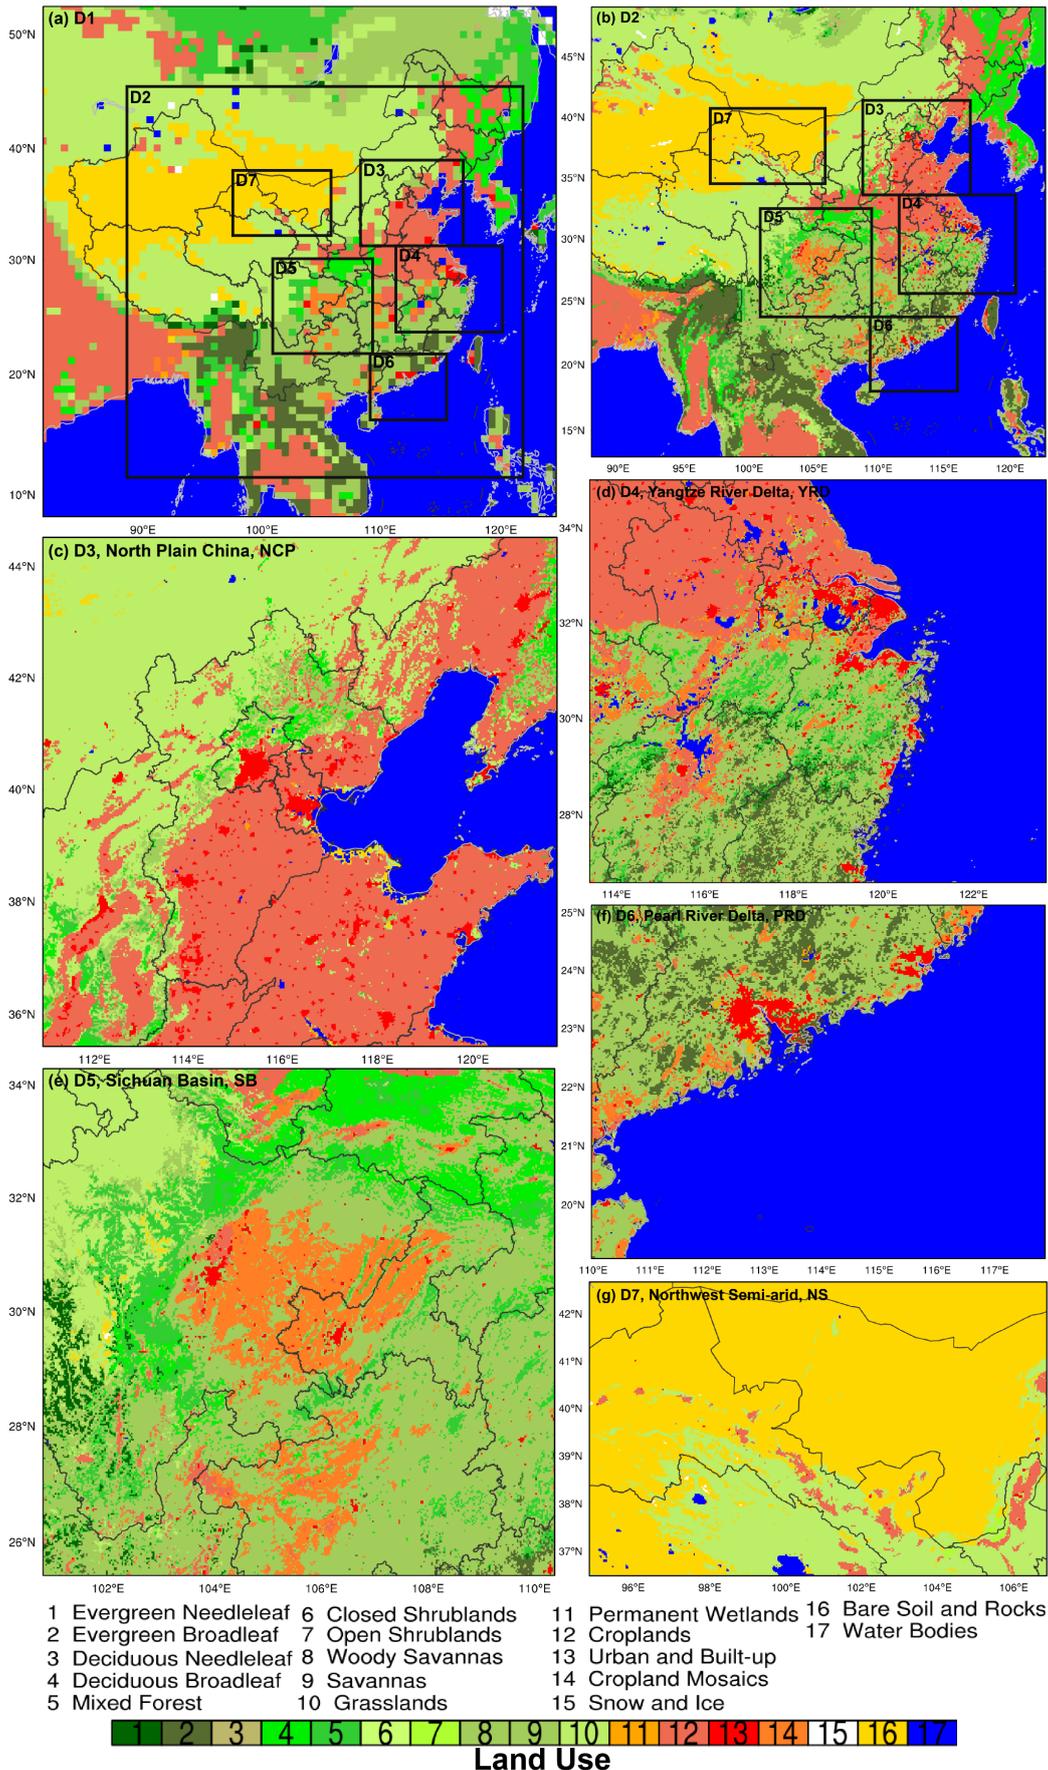

371

372 Figure 13. Regional distribution of 2-m relative humidity simulated by the (a) FNL-0.25°, (b) EC-
 373 0.25° and (c) FNL-1° for five regions in January, and the blue dashed circles indicate the regions
 374 where the results of the three experimental simulations differ significantly.

375 In the vertical direction, the simulated results of the three experiments for temperature and wind
376 speed do not differ much, unlike the near-surface meteorological parameters (i.e., T_2 , RH_2 , WS_{10}
377 and WD_{10}) that show such obvious differences (Fig. S1, S2). Nevertheless, for the relative humidity,
378 the variation in vertical direction at different heights is more consistent with the near-surface layer,
379 where the relative humidity of EC data is high in the whole layer (Fig. S3). Except for a few highland
380 stations outside the basin in the SB region, the relative humidity of EC data is low at higher altitudes
381 (Fig. S3 a3, b3, d3).

382 3.5 effect of underlying surface on meteorological parameters

383 To further explore the impact of underlying surface changes on the simulation results of
384 meteorological fields, we use the underlying surface data in January 2016 that is closer to the
385 simulation time, in addition to the default underlying surface data that comes with the model, for
386 comparative analysis of the simulation. Comparing figure 1 and figure 14, it can be concluded that
387 the most substantial change in the Domain 1 area is in the croplands type (i.e., code 12), especially
388 for the area south of latitude 30 °N. Many types with an underlying surface of 12 have become 14
389 or 8, 9 etc. Although both 12 and 14 here can represent cropland, there are some differences in the
390 specific descriptions. Code 12 mainly indicates that at least 60% of area is cultivated cropland, while
391 code 14 mainly refers to the mosaics of small-scale cultivation 40–60% with natural tree, shrub, or
392 herbaceous vegetation. In addition to croplands, the two types of urban and water bodies are more
393 variable as well. Therefore, this subsection focuses on the effects of urban and water body changes
394 on surface meteorological fields.

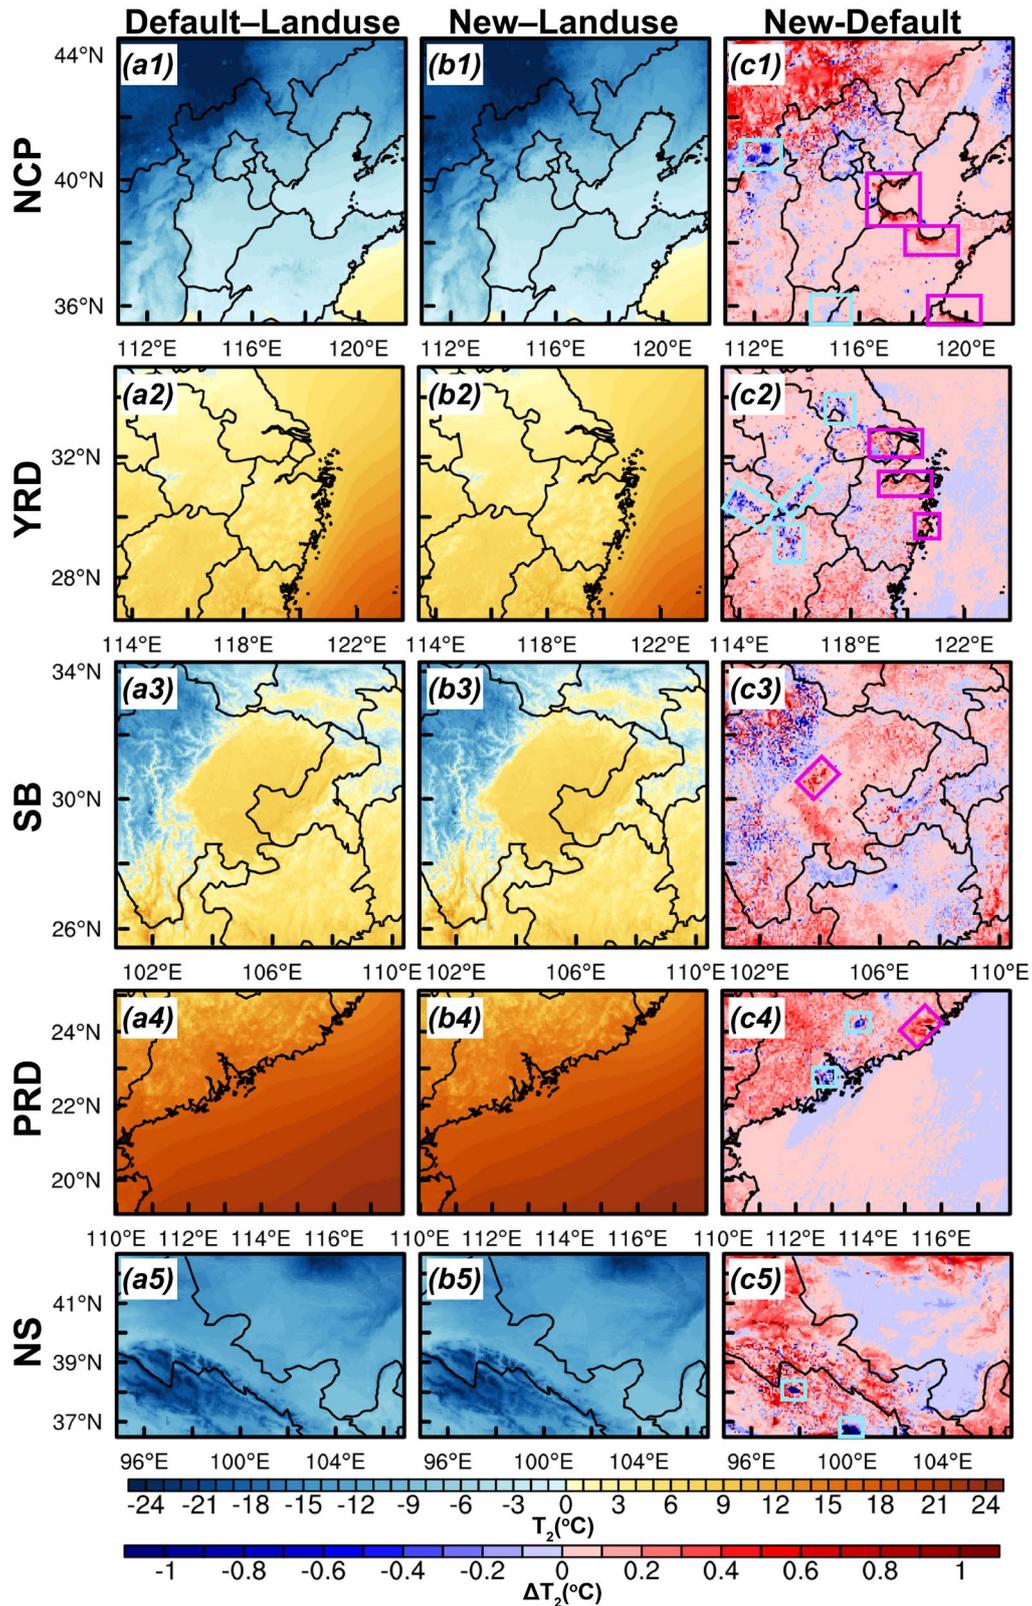

395
396

Figure 14. Similar as figure 1, but for the land use type for January 2016.

397 In terms of the overall regional distribution, the new underlying surface did not affect the areas of
398 high and low values of temperature (Fig. 15 a-b) to an important degree. However, the difference
399 between the simulation results of two different underlying surface shows that the change of the
400 underlying surface has an effect on the temperature by about ± 1 °C, especially for the grids with
401 more obvious changes in water bodies and urban areas (Fig. 15 c). In the NCP region, an increase
402 in the area of water bodies in the coastal areas of Tianjin (TJ) Shi, Shandong (SD) province, and
403 Jiangsu (JS) province leads to a distinct increase in temperature (i.e., indicated by red boxes), while
404 a decrease in the area of inland water in the northern region of Shanxi (SX) province causes a
405 decrease in temperature (i.e., denoted by blue boxes) (Fig. 15 c1). The decrease in the area of water
406 bodies in the Yangtze River in the YRD region has caused a decrease in temperature, while
407 urbanization has contributed to an increase in temperature in several regions (Fig. 15 c2). The
408 underlying surface changes in the SB region are mainly in the form of forest and savannas changes,
409 as well as the more rapid urbanization of the provincial capital city of Chengdu (CD) Shi (Fig. 14
410 e). The development of this city has a positive feedback effect on the temperature of the region (Fig.
411 15 c3). The underlying surface change in the YRD region is from croplands to savannas, with a
412 rapid greening rate, and its excessive greening may make the green coverage of some cities too high,
413 leading some grids to identify the cities as savannas. In the NS region, the area of croplands and
414 cities along the Qilian Mountains increases and the area of some inland lakes decreases, in turn
415 leaving some influence on the results of the temperature.

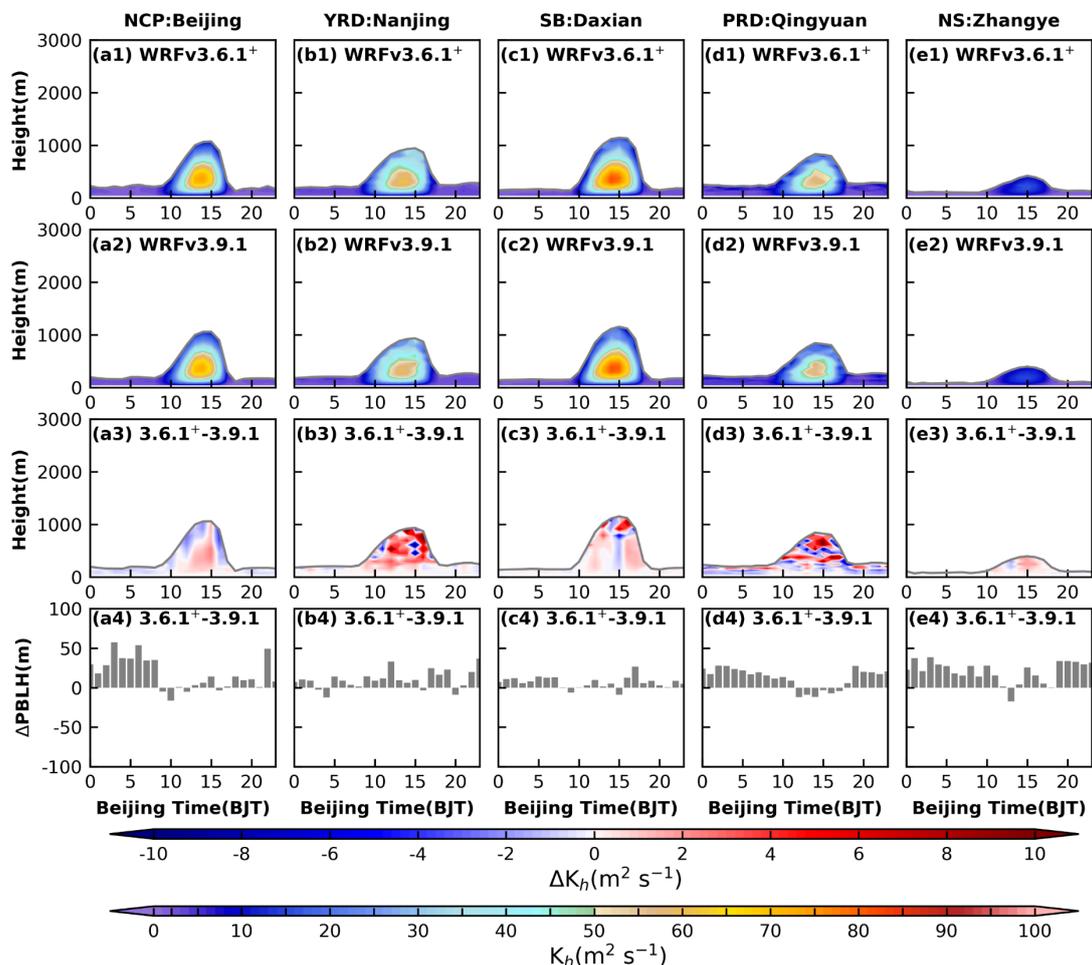

416 The wind field does not vary as regularly as the temperature field. Except for the variation of water
417 body area which has a more consistent pattern on the wind field, all other types of underlying surface
418 variation have a haphazard effect on the wind field (Fig. S4).

419
 420 Figure 15. Regional distribution of 2-m temperature simulated by the (a) default land use, (b) new
 421 land use and (c) the difference between the two land use types for five regions in January. The blue
 422 (red) box indicates the region where the wind speed decreases (increases) due to changes in the
 423 water bodies and urban.

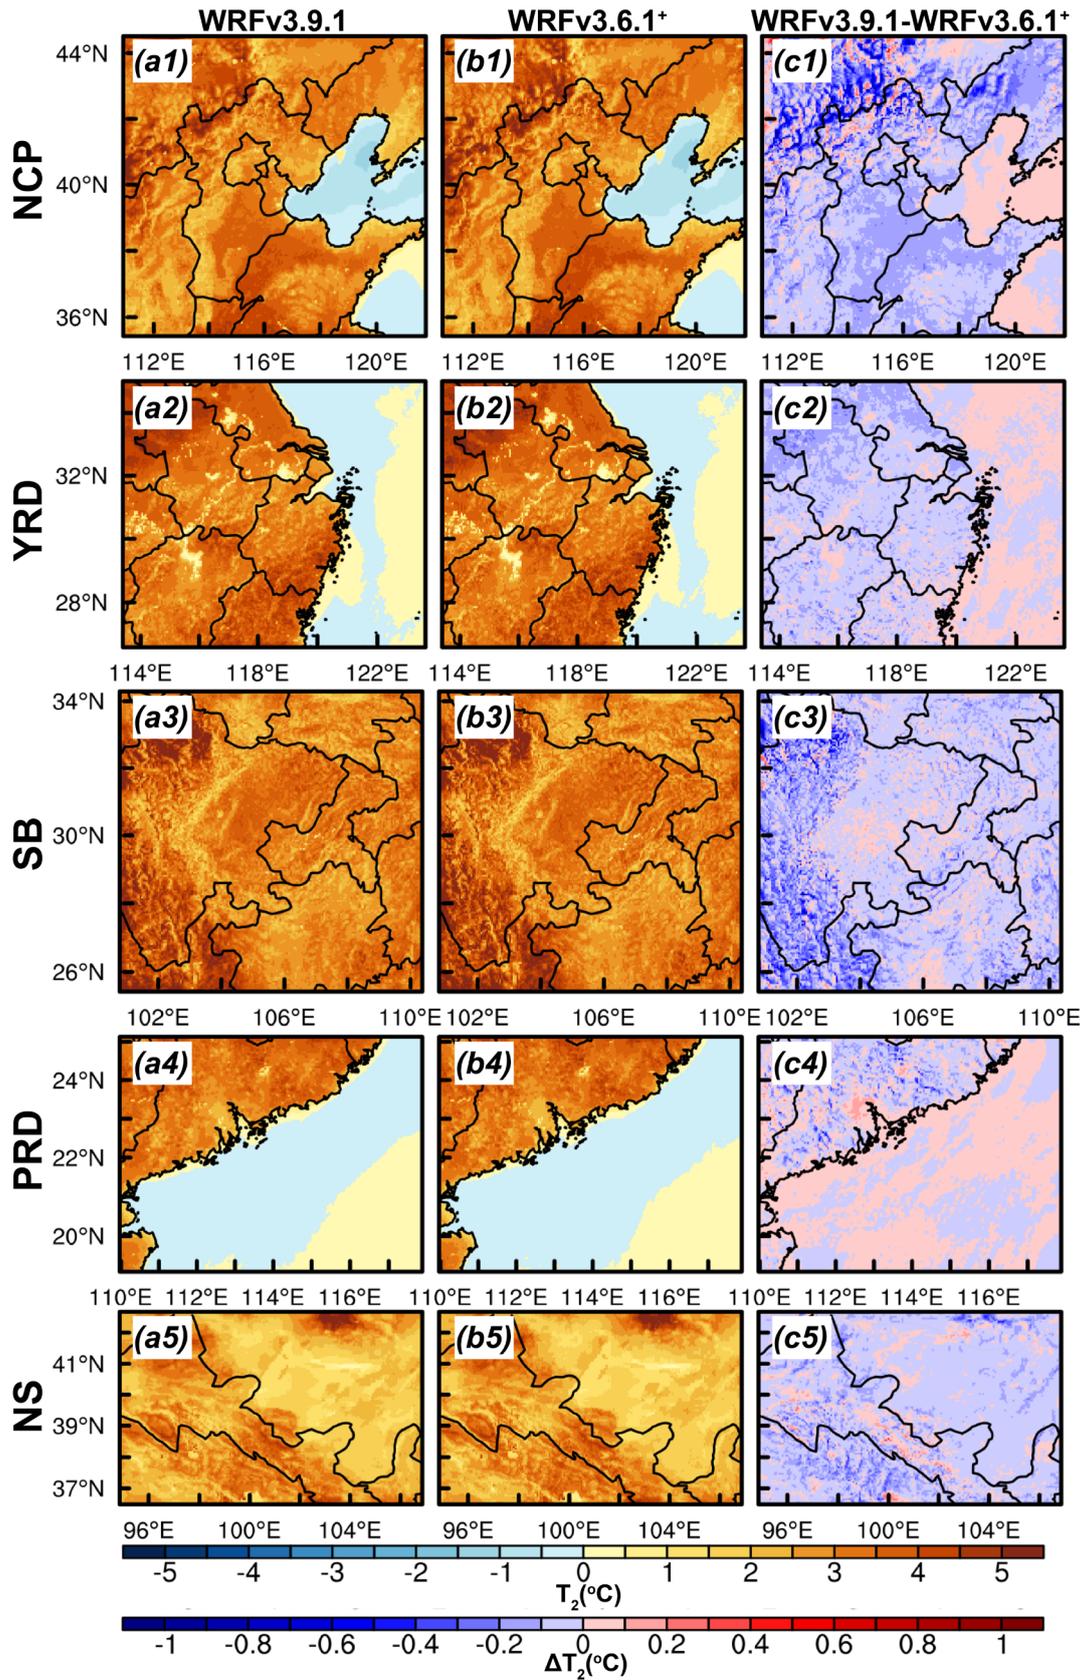

424 **3.6 impact of the model version update**

425 As computer technology continues to evolve, the parameterizations in the model are being upgraded
 426 and improved, but it is worthwhile further exploring how much the parameterizations and versions
 427 affect the simulation results of the model. For the PBL parameterization scheme, turbulent diffusion
 428 is crucial for the vertical mixing of momentum, heat, water vapor and pollutants within the PBL.
 429 And in December 2014, the ACM2 parameterization scheme received two major updates: (1) The
 430 turbulent diffusion coefficients of heat are updated. The stability function of Richardson number is
 431 modified, expecting to reduce the day and night 2-m temperature bias. (2) The bug that the minimum
 432 value of the PBLH is lower than the height of the first level of the model under stable conditions
 433 has been restored, and the minimum value of the PBLH is fixed to the height of the first level of the
 434 model. We, therefore, choose the ACM2 scheme in WRFv3.6.1 as a control experiment. In the
 435 control experiment, the ACM2 scheme in the WRFv3.9.1 version is replaced with WRFv3.6.1, and
 436 all other schemes are kept in the WRFv3.9.1 (i.e., WRFv3.6.1⁺). This ensures that the difference
 437 between the two experiments is the representative of the impact of the ACM2 scheme update.

438

439 Figure 16. Time-height cross sections of heat turbulent diffusion coefficient (TDC) simulated by
440 (a1-e1) WRFv3.6.1+, (a2-e2) WRFv3.9.1, (a3-e3) the difference between the TDC of the two versions.
441 (a4-e4) Time series of diurnal variation of the difference between the PBLH of the two versions.
442 The gray line in (a1-e3) indicates the PBLH.
443

444

445

446

Figure 17. Regional distribution of diurnal 2-m temperature range simulated by the (a) WRFv3.9.1, (b) WRFv3.6.1⁺ and (c) the difference between the two versions for five regions in January.

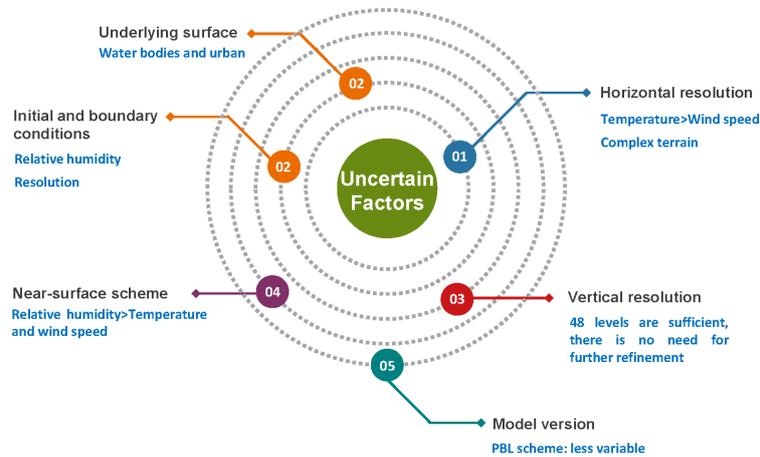

447 The difference between the turbulent diffusion coefficient of heat calculated by the two versions lies
448 in the different principles of calculation using the Richardson number (Ri) method. In the
449 WRFv3.6.1⁺, not only Ri is used to judge the stability, but also z/L is used to additionally constrain
450 the stability and determine the empirical stability function. In contrast, only Ri is adopted to
451 determine the function in the WRFv3.9.1. Figure 16 shows the diurnal variation of turbulent
452 diffusion coefficient of heat with height, as well as the difference of PBLH. In general, the two
453 versions have no effect on the overall trend of TDC (Fig. 16 a1-e2). However, within the PBL, the
454 TDC of WRFv3.9.1 is smaller than that of WRFv3.6.1⁺, with the most significant difference during
455 the daytime. Meanwhile, in some regions at night, a TDC of WRFv3.9.1 is also greater than that of
456 WRFv3.6.1⁺ (Fig. 16 a3-e3). Besides, the differences among the five regions slightly vary. The
457 deviation in the NCP, SB, and NS regions is small, around $2 \text{ m}^2 \text{ s}^{-1}$ (Fig. 16 a3, c3, e3), while the
458 deviation in the YRD and PRD regions is large, up to about $10 \text{ m}^2 \text{ s}^{-1}$ (Fig. 16 b3, d3). The TDC
459 modification aims to reduce the temperature difference between day and night. Indeed, this
460 expectation is fulfilled. It can be noticed in figure 17, the diurnal temperature difference for
461 WRFv3.9.1 is smaller than that of WRFv3.6.1⁺ in almost all regions (except for the area where the
462 underlying surface is water). In addition, we need to pay attention to the variation of the PBLH. As
463 shown in figure 16, the difference in PBLH during daytime is smaller than at night, and the PBLH
464 of WRFv3.9.1 is lower than that of WRFv3.6.1⁺. The model WRFv3.9.1 fixes the minimum value
465 of the PBLH to the first level height, markedly reducing the PBLH at night. But this approach may
466 be too crude and parsimonious to cause problems, and should be corrected in the future.

467 **4 Conclusion**

468 The simulation results of the model within the PBL are subject to many factors, but its portrayal and
469 description by the PBL parameterization schemes plays a vital role in affecting the variation of the
470 meteorological field. The simulations of the PBL schemes on the meteorological fields has been
471 described in Part I. In Part II, further uncertainties affecting the results of the meteorological field
472 are evaluated and analyzed, and the degree of influence of different factors is compared, hoping to
473 provide a reference for scholars conducting research on the model.

474 In addition to the dominant role of the PBL scheme on the results of the meteorological field, many
475 elements in the model are influenced by large uncertainties. For example, what is the effect of
476 horizontal resolution, and how much does the result vary under different resolution conditions? Is

477 the continuous encryption of the vertical levels necessary for the simulation of the vertical structure
 478 of the PBL? Which has a greater impact on the results of the meteorological field, the near-surface
 479 (N-S) layer scheme or the PBL scheme? How much is the impact of these changes on the underlying
 480 surface, which is constantly updated by the development of urbanization? The innovation of
 481 computer technology has brought the opportunity to keep the model being updated. How much
 482 effect will the updates have on different versions of the model results? The simulation of the model
 483 depends on the initial and boundary conditions, so how much does the initial and boundary
 484 conditions of different resolutions and products affect the model results? These uncertainties have
 485 not been fully evaluated and analyzed yet. To resolve the confusions, this study synthesizes the
 486 effects of the above factors on the model results.

487
 488 **Figure 18. An overview figure of the prioritization of uncertainties, where the uncertainties are in**
 489 **black font and the elements focused on in that factor are in blue font.**

- 490 *a. Effect of the horizontal resolution.* The three different resolutions have a more dramatic effect
 491 on temperature than on wind speed (Fig. 18). Regardless of the region, the distribution of
 492 temperature deviations simulated at 75 km resolution is clearly different from that of 15 km and
 493 3 km, especially in areas with more complex topography, such as NCP, SB and NS regions. All
 494 three resolutions overestimate the wind speed in all regions, except for the 75 km resolution,
 495 where there is an underestimation of the wind speed at the stations around the basin in the SB
 496 region (Fig. 18). The difference between the resolutions decreases with increasing temperature,
 497 but becomes more pronounced with increasing wind speed.
- 498 *b. Effect of the vertical resolution.* The number of vertical levels of the model is encrypted from
 499 48 to 62 levels, with almost no effect on the vertical structure of the PBL. Meanwhile, the
 500 increase in the number of vertical levels brings into an increase in memory of about 150 GB for
 501 one month. Compared to the horizontal resolution, the vertical resolution does not need to be

502 set particularly fine, and 48 levels are perfectly sufficient to reproduce the evolution of the PBL
503 structure (Fig. 18).

504 *c. Influence of the N-S scheme.* The PBL scheme makes a greater impact on the simulated results
505 for temperature, wind speed and direction, while for relative humidity, the N-S scheme
506 contributes largely, especially in the NCP, SB and NS regions. For either scheme, the effect is
507 much greater at night than during the daytime. In general, the choice of the PBL scheme is more
508 critical for temperature and wind fields. But for relative humidity, the PBL and N-S schemes
509 are equally important (Fig. 18).

510 *d. Impact of the initial and boundary conditions.* The effect of data of different resolutions of the
511 same product on the results of temperature and relative humidity is small, but the influence of
512 data of different products of the same resolution is large. EC data simulates temperature better
513 than FNL data during the daytime, while at night, the difference between the two data is
514 relatively small (except for the NCP and NS regions). The EC data simulate the relative
515 humidity better than the FNL data regardless of the region, even in the vertical direction, which
516 will expose a key way to improve the relative humidity results of the model in the future (Fig.
517 18). Nonetheless, data of the same resolution but different products exhibit no obvious effect
518 on wind speed, while the influence of data from the same product with different resolutions is
519 larger, especially at night.

520 *e. Effect of the underlying surface.* In terms of regional distribution, the new underlying surface
521 make no significant difference with respect to the temperature. However, for the grids with
522 more pronounced changes in water bodies and urban, the change in underlying surface has an
523 approximate $\pm 1^\circ\text{C}$ influence on temperature (Fig. 18). An increase (decrease) in the area of
524 water bodies leads to an increase (decrease) in temperature, and the growth of urbanization
525 brings about an increase in temperature. The variation of wind field is not as regular as
526 temperature. Except for the changes in the area of water bodies that affect the wind field
527 consistently, other types of underlying surface changes show a haphazard effect on the wind
528 field.

529 *f. Influence of the model version.* The update of the PBL scheme reduces the day and night 2-m
530 temperature bias. But the simple definition method of fixing the minimum value of the PBLH
531 as the first level height of the model may have some defects. The change in the stability function
532 of the Richardson number alters the turbulent diffusion coefficient of heat, which is more

533 distinct in the daytime with a deviation of about $10 \text{ m}^2 \text{ s}^{-1}$. The PBL parameterization scheme
534 in the current model is less modified (Fig. 18).
535 In summary, the horizontal resolution is more influential than the vertical resolution. The N-S
536 scheme has less effect than the PBL scheme on the results of temperature and wind speed. Also,
537 the initial and boundary conditions of different products have the most significant influence on
538 relative humidity. Grid changes where the underlying surface is urban and water bodies have a
539 more pronounced effect on the results of meteorological fields, especially for temperature. The
540 PBL parameterization schemes in the version WRFv3.9.1 and WRFv3.6.1 are less changed and
541 have less impact on the simulation of model results. (Fig. 18). A special advice here is that the
542 needs of different scholars for the model vary a lot, thus, the configuration of uncertainties
543 requires a comprehensive consideration to obtain the optimal results for the analysis.

544 **Code and data availability**

545 The source codes of WRF version 3.9.1 and 3.6.1 can be found on the following website:
546 <https://www2.mmm.ucar.edu/wrf/users/download/>. The original model settings file is already
547 included in Supplement in Part I, while the other model settings file used in Part II is named after
548 the file name “L62_namelist.input” and is already included in Supplement. In addition, the
549 observations used are also provided in Supplement in Part I. The initial field and boundary condition
550 data and the underlying surface data are provided in the text.

551 **Author contributions**

552 Development of the ideas and concepts behind this work was performed by all the authors. Model
553 execution, data analysis and paper preparation were performed by WJ. XZ and HW provide
554 computing resources, and offer advice and feedback. YW, DW, and JZ support the data. WZ, LZ,
555 LG, YL, JW, YY, and YL provides suggestions. All authors contributed to the manuscript.

556 **Competing interests**

557 The authors declare that they have no conflict of interest.

558 **Acknowledgements.**

559 The work was carried out at the National Supercomputer Center in Tianjin, and the calculations
560 were performed on TianHe-1 (A).

561 **Financial support**

562 This research is supported by NSFC Major Project (42090031), NSFC Project (U19A2044), Basic
563 Research Fund of CAMS (2023Y003).
