Abstract

A single ozone (O₃) tracer mode was developed in this work to build the capability of the GEOS-Chem model for rapid O₃ simulation. The single O₃ tracer simulation demonstrates consistency with the GEOS-Chem full chemistry simulation, with dramatic reductions in computational costs of approximately 91-94%. The single O₃ tracer simulation was combined with surface and Ozone Monitoring Instrument (OMI) O₃ observations to investigate the changes in tropospheric O₃ over eastern (E.) China in 2015-2020. The assimilated O₃ concentrations demonstrate good agreement with O₃ observations: surface O₃ concentrations are 43.2, 41.8 and 42.1 ppb, and tropospheric O₃ columns are 37.1, 37.9 and 38.0 DU in the simulations, assimilations and observations, respectively. The assimilations indicate rapid rises in surface O₃ concentrations by 1.60 (spring), 1.16 (summer), 1.47 (autumn) and 0.80 (winter) ppb yr⁻¹ over E. China in 2015-2020, and the increasing trends are underestimated by the a priori simulations. More attention is suggested to the rapid increases in O₃ pollution in spring and autumn. We find stronger rises in tropospheric O₃ columns over highly polluted areas due to larger local contributions, for example, 0.12 DU yr⁻¹ (North China Plain) in contrast to -0.29 (Sichuan Basin) -0.25 DU yr⁻¹ (Southern China). Furthermore, our analysis demonstrated noticeable contributions of the interannual variability in background O₃ to the trends in surface O₃ (particularly in the summer) and tropospheric O₃ columns over E. China in 2015-2020. This work highlights the importance of rapid simulations and assimilations to extend and interpret

32 atmospheric O₃ observations.

33

34 **1. Introduction**

35 Tropospheric ozone (O₃) is produced when volatile organic compounds (VOCs) and
36 carbon monoxide (CO) are photochemically oxidized in the presence of nitrogen oxides (NO_x).
37 Tropospheric O₃ has important influences on the climate (Mickley, 2004; Iglesias-Suarez et al.,
38 2018), atmospheric oxidation capacity (Thompson, 1992; Prinn, 2003), human health and crop
39 growth (Zhang et al., 2021; Li et al., 2022). The important role of O₃ in the atmosphere has led
40 to many efforts focusing on O₃ observations that have improved our understanding of
41 atmospheric O₃ (Logan et al., 2012; Oetjen et al., 2016; Parrish et al., 2021). The limited spatial
42 coverage of O₃ observations promotes the efforts of spatial extensions of O₃ observations
43 (Chang et al., 2015; Peng et al., 2016). Recent advances in machine learning techniques further
44 provide a new method to extend O₃ observations by fusing satellite and surface observations
45 (Li et al., 2020; Liu et al., 2022; Wei et al., 2022).

46 Chemical transport models (CTMs), as powerful tools, have been widely used to simulate
47 and interpret observed O₃ variabilities (Parrington et al., 2012; Jiang et al., 2016; Li, Ke et al.,
48 2019). Despite the advances in CTMs, an accurate simulation of observed O₃ is still challenging
49 because of uncertainties in physical and chemical processes (Peng et al., 2021; Chen et al.,
50 2022), emission inventories (Elguindi et al., 2020; Jiang et al., 2022) and coarse model
51 resolutions (Schaap et al., 2015; Benavides et al., 2021). Furthermore, the high computational
52 cost is a bottleneck for rapid simulations, which poses a possible barrier to better understanding
53 tropospheric O₃. Alternatively, researchers may consider simulations of atmospheric O₃ with
54 the archived O₃ product and loss rates. For example, the tagged-O_x mode of the GEOS-Chem
55 model has been used to analyze the sources and transport of tropospheric O₃ (Zhang et al., 2008;
56 Zhu et al., 2017; Han et al., 2018). However, it may not be an ideal choice to perform O₃

57 simulations based on the tagged-O_x mode because O_x is the combination of multiple species,
58 including O₃, and thus cannot be accurately compared with O₃ observations.

59 In this study, we developed the single O₃ tracer mode (tagged-O₃) of the GEOS-Chem
60 model, driven by archived O₃ product and loss rates provided by GEOS-Chem full chemistry
61 simulations, to build the capability of the GEOS-Chem model for rapid simulations of
62 tropospheric O₃ (rather than O_x). Data assimilations, by combining modeled and observed O₃
63 concentrations, can take advantage of both simulations and observations to produce more
64 accurate O₃ concentrations (Parrington et al., 2008; Ma et al., 2019; Huijnen et al., 2020). The
65 single O₃ tracer simulations were thus further combined with the Ozone Monitoring Instrument
66 (OMI) and China Ministry of Ecology and Environment (MEE) monitoring network O₃
67 observations (in this paper) and United States (US) Air Quality System (AQS) and European
68 AirBase network O₃ observations (in the companion paper, Zhu et al. (2023)) via a sequential
69 Kalman Filter (KF) assimilation system (Tang et al., 2022; Han et al., 2022) to perform a
70 comparative analysis to investigate the changes in tropospheric O₃ in eastern (E.) China in
71 2015-2020 (in this paper) and the US and Europe in 2005-2020 (Zhu et al., 2023).

72 Satellite instruments provide globally covered O₃ observations that are sensitive to O₃
73 concentrations in the free troposphere. The OMI-based assimilations can thus reflect the
74 optimized adjustments in both global background and local O₃ concentrations. On the other
75 hand, surface observations are sensitive to local O₃ concentrations. Surface observation-based
76 assimilations can reflect the optimized adjustments in local contributions, and the information
77 of local contributions can be transported into the free troposphere via vertical convection in the
78 assimilation processes, which is different from the fusion of satellite and surface observations
79 (Li et al., 2020; Liu et al., 2022; Wei et al., 2022). Consequently, a comparative analysis by
80 assimilating satellite and surface O₃ observations is useful for better characterization of O₃
81 changes in the surface and free troposphere. Furthermore, the low computational costs of the

82 single O₃ tracer simulations allow us to design and perform different experiments much more
83 efficiently. Multiple simulation and assimilation experiments (see details in Table 1) were thus
84 conducted in this work to analyze the impacts of background O₃ (particularly, the interannual
85 and seasonal variabilities in the background O₃ as well as optimization in the background O₃)
86 and local O₃ formation on the changes in surface and free tropospheric O₃ over E. China.

87 This paper is organized as follows: in Section 2, we provide descriptions of the MEE and
88 OMI O₃ observations, the GEOS-Chem model and the single O₃ tracer simulation and
89 assimilation system used in this work. Tropospheric O₃ changes in E. China in 2015-2020 are
90 then demonstrated in Section 3 by assimilating MEE and OMI O₃ observations. As shown in
91 Fig. 1, five regions (i.e., North China Plain (#1), Yangtze River Delta (#2), Central China (#3),
92 Sichuan Basin (#4) and Southern China (#5)) are defined within the E. China domain. Regions
93 #1 and #2 are defined as highly polluted regions by excluding grids with low and medium
94 anthropogenic NO_x emissions. Tropospheric O₃ changes over these regions are discussed to
95 investigate the possible regional discrepancies in surface and free tropospheric O₃ associated
96 with different local pollution levels. Our conclusions follow in Section 4.

97

98 **2. Data and Methods**

99 **2.1 Surface O₃ measurements**

100 We use MEE surface in situ O₃ concentration data (<https://quotsoft.net/air/>) for the period
101 2015-2020. These real-time monitoring stations report hourly concentrations of criteria
102 pollutants from 1691 sites in 2020. All stations (1441 urban sites and 250 urban background
103 sites) are assimilated in our analysis. Concentrations were reported by the MEE in $\mu\text{g m}^{-3}$ under
104 standard temperature (273 K) until 31 August 2018. This reference state was changed on 1
105 September 2018 to 298 K. We converted the O₃ concentrations to ppb and rescaled the post-
106 August 2018 concentrations to the standard temperature (273 K) to maintain consistency in the

107 trend analysis. It should be noted that the assimilation of O₃ observations from urban and urban
108 background sites may result in possible overestimation of surface O₃ concentrations over rural
109 areas.

110 **2.2 OMI PROFOZ product**

111 The OMI instrument was launched in July 2004 on the Aura spacecraft with a spatial
112 resolution of 13 × 24 km (nadir view). It provides globally covered measurements with
113 backscattered sunlight in the ultraviolet–visible range from 270 to 500 nm (UV1: 270–310 nm;
114 UV2: 310–365 nm; visible: 350–500 nm). In this study, we use the OMI O₃ profile retrieval
115 product (PROFOZ v0.9.3, level 2, Liu et al. (2010); Huang et al. (2017)) from the Smithsonian
116 Astrophysical Observatory (SAO). The retrieval uses the vector linearized discrete ordinate
117 radiative transfer model (VLIDORT) (Spurr, 2006) and Bayesian optimal estimation. Profiles
118 of partial O₃ columns (unit: DU) are retrieved in the spectral region of 270–330 nm with 24
119 vertical layers: approximately 2.5 km for each layer from the surface to approximately 60 km.
120 The following filters are applied in our analysis following Huang et al. (2017): 1) nearly clear-
121 sky scenes with effective cloud fraction < 0.3; 2) solar zenith angles (SZA) < 75°; and 3) fitting
122 root mean square (RMS, ratio of fitting residuals to assumed measurement error) < 2.0.

123 Starting in 2009, anomalies were found in the OMI data and diagnosed as attenuated
124 measured radiances in certain cross-track positions. This instrument degradation has been
125 referred to as the “row anomaly”. To enhance the quality and stability of the data, only across-
126 track positions between 4-11 (within 30 positions in the UV1 channels) are assimilated in our
127 main assimilation experiment (Exp. #8). This treatment is similar to the production of row-
128 isolated data by using across-track positions between 3-18 (within 60 positions in the UV2
129 channels) in the OMI/MLS O₃ data (Ziemke et al., 2019; Wang, X. et al., 2022). The effects of
130 the usage of row-isolated data will be evaluated by comparing the main assimilation experiment
131 with the sensitivity assimilation experiment (Exp. #10) by assimilating OMI O₃ observations

132 at across-track positions 4-27.

133 The modeled tropospheric O₃ profiles in the assimilation processes and subsequent
134 analyses are convolved by using the OMI retrieval averaging kernels and a priori O₃ profile
135 based on the following equation (Liu et al., 2010; Huang et al., 2017):

$$136 \quad \hat{\mathbf{x}} = \mathbf{x}_a + \mathbf{A}(\mathbf{x} - \mathbf{x}_a) \quad (\text{Eq. 1})$$

137 where $\hat{\mathbf{x}}$ is the modeled O₃ profile convolved by the retrieval averaging kernels, \mathbf{x}_a is the
138 OMI a priori O₃ profile, \mathbf{x} is the modeled O₃ profile, and \mathbf{A} is the OMI averaging kernel
139 matrix. Here $A(i, j) = \frac{\partial \hat{x}_j}{\partial x_i}$, representing the sensitivity of the retrieved partial O₃ column (DU)
140 at layer j to the change in O₃ (DU) at layer i. The unit for averaging kernels in this OMI product
141 is DU/DU because the conversion from DU to ppb varies with altitude.

142 **2.3 GEOS-Chem model configuration**

143 The GEOS-Chem chemical transport model (<http://www.geos-chem.org>, version 12-8-1)
144 is driven by assimilated meteorological data from MERRA-2. The GEOS-Chem full chemistry
145 simulation includes fully coupled O₃-NO_x-VOC-halogen-aerosol chemistry. Our analysis is
146 conducted at a horizontal resolution of nested 0.5°×0.625° over E. China with chemical
147 boundary conditions archived every 3 hours from global simulations with 4°×5° resolution.
148 Emissions are computed by the Harvard-NASA Emission Component (HEMCO). Global
149 default anthropogenic emissions are from the CEDS (Community Emissions Data System)
150 (Hoesly et al., 2018). Regional emissions are replaced by MEIC (Multiresolution Emission
151 Inventory for China) in China and MIX in other regions of Asia (Li et al., 2017). The reference
152 year for the CEDS inventory is 2010 with annual scaling factors in 2005-2014, and the
153 reference year for the MEIC/MIX inventory is 2010 with annual scaling factors in 2008-2010
154 in the GEOS-Chem model. Open fire emissions are from the Global Fire Emissions Database
155 (GFED4) (van der Werf et al., 2010).

156 Following Jiang et al. (2022), the total anthropogenic NO_x and VOC emissions in the
157 GEOS-Chem model are scaled based on Zheng et al. (2018) and Li, M. et al. (2019) so that the
158 modeled surface nitrogen dioxide (NO₂) and O₃ concentrations in the a priori simulations are
159 identical to Jiang et al. (2022) in 2005-2018. The total anthropogenic NO_x and VOC emissions
160 in 2019-2020 are further scaled based on linear projections. The total anthropogenic NO_x
161 emissions in the a priori simulations declined by 19% in China in 2015-2020. The total
162 anthropogenic VOC emissions in the a priori simulations increased by 1% in China in 2015-
163 2020. We refer the reader to Jiang et al. (2022) for the details of the model configuration and
164 performance, particularly the modeled trends of surface and tropospheric column NO₂ in 2005-
165 2018.

166 **2.4 Single O₃ tracer simulation**

167 A new chemical mechanism was developed in this work to allow the running of the single
168 O₃ tracer mode (tagged-O₃). As shown in Fig. S1 (see the SI), the package of the Kinetic
169 PreProcessor (KPP) module was modified to define the production (PO₃) and loss (LO₃) of O₃.
170 The GEOS-Chem full chemistry simulations with the updated KPP module were then
171 performed to produce PO₃ and LO₃ every 20 minutes. Here the 20 minutes are selected to be
172 the same as the chemical time step in the GEOS-Chem full chemistry mode to ensure
173 consistency between the single O₃ tracer and full chemistry simulations. Finally, the single O₃
174 tracer simulation (tagged_o3_mod.F90) was performed by reading the archived PO₃ and LO₃
175 provided by the full chemistry simulations. Because we are interested in tropospheric
176 chemistry, we archived O₃ concentrations instead of O₃ production and loss rates in the
177 stratosphere in the full chemistry simulations. The archived stratospheric O₃ concentrations
178 were read in the single O₃ tracer simulation process as boundary conditions to ensure a
179 reasonable stratospheric-tropospheric O₃ exchange.

180 The major advantage of the single O₃ tracer simulation is dramatic reductions in

181 computational costs by approximately 91%-94%; for example, the computational costs (hours
182 of wall time for one year simulation) are 57.5 and 5.2 hours at the global scale ($4^\circ \times 5^\circ$) and 80.2
183 and 4.5 hours within the nested China domain ($0.5^\circ \times 0.625^\circ$) by full chemistry and single O_3
184 tracer simulations, respectively. Consequently, once PO_3 and LO_3 are produced, the
185 computational costs of performing additional single O_3 tracer simulations are almost negligible.
186 The low computational costs of the single O_3 tracer simulation allow us to design and perform
187 different simulation and assimilation experiments much more efficiently. As shown in Table
188 1, there are 10 different simulation and assimilation experiments performed in this work, which
189 requires 4812 hours (wall time) with the full chemistry simulation but only 270 hours (wall
190 time) with the single O_3 tracer simulation.

191 Here we evaluate the consistency in modeled O_3 concentrations between single O_3 tracer
192 and full chemistry simulations. Fig. 2A1-A5 show the annual and seasonal averages of the
193 surface maximum daily 8-hour average (MDA8) O_3 over E. China in 2015-2020 from the full
194 chemistry simulation. The modeled surface MDA8 O_3 concentrations are as high as 60-70 ppb
195 in the summer and as low as 10-20 ppb in the winter over northern China. The simulation with
196 the single O_3 tracer mode (Fig. 2B1-B5) demonstrates spatial consistency with the full
197 chemistry simulation (Fig. 2A1-A5) and temporal consistency at both the daily (Fig. 3A) and
198 monthly (Fig. 3B) scales in 2015-2020. In contrast, the tagged- O_x mode of the GEOS-Chem
199 model is driven by the archived production and loss of O_x , which is the combination of multiple
200 species ($O_x = O_3 + NO_2 + 2NO_3 + 3N_2O_5 + HNO_3 + HNO_4 +$ peroxyacylnitrates). There are large
201 discrepancies between full chemistry (Fig. 2A1-A5) and tagged- O_x (Fig. 2C1-C5) simulations.
202 As shown in Fig. 3, the O_x concentrations are higher than the O_3 concentrations by
203 approximately 6 ppb, and the relative difference can reach 40% in the winter. Our analysis thus
204 indicates the reliability of the single O_3 tracer simulations developed in this work.

205 **2.5 Data assimilation method**

206 We employ the sequential KF to assimilate O₃ observations, which has been used in
 207 recent studies to optimize tropospheric CO concentrations (Tang et al., 2022; Han et al., 2022).
 208 As a brief description of the assimilation algorithm, the forward model (**M**) predicts the O₃
 209 concentration (\mathbf{x}_{at}) at time t:

$$210 \quad \mathbf{x}_{at} = \mathbf{M}_t \mathbf{x}_{t-1} \quad (\text{Eq. 2})$$

211 The optimized O₃ concentrations can be expressed as:

$$212 \quad \mathbf{x}_t = \mathbf{x}_{at} + \mathbf{G}_t (\mathbf{y}_t - \mathbf{K}_t \mathbf{x}_{at}) \quad (\text{Eq. 3})$$

213 where \mathbf{y}_t is the observation and \mathbf{K}_t represents the operation operator that projects O₃
 214 concentrations from the model space to the observation space. \mathbf{G}_t is the KF gain matrix, which
 215 can be described as:

$$216 \quad \mathbf{G}_t = \mathbf{S}_{at} \mathbf{K}_t^T (\mathbf{K}_t \mathbf{S}_{at} \mathbf{K}_t^T + \mathbf{S}_\epsilon)^{-1} \quad (\text{Eq. 4})$$

217 where \mathbf{S}_{at} and \mathbf{S}_ϵ are the model and observation covariances, respectively. The optimized O₃
 218 concentrations provided by Eq. 3 are then forwarded (hourly) to Eq. 2. The model errors are
 219 assumed to be 50% because the objective of our assimilations is to provide dynamic extensions
 220 of atmospheric O₃ observations. The a posteriori O₃ concentrations with the assumption of 50%
 221 model errors are expected to match better with atmospheric O₃ observations. The measurement
 222 errors are calculated as $\epsilon_0 = ermax + 0.0075 * \Pi_0$, where *ermax* is the base error (1.5 $\mu\text{g m}^{-3}$)
 223 and Π_0 represents the observed O₃ concentrations (unit: $\mu\text{g m}^{-3}$). The representation errors
 224 are calculated as $\epsilon_r = \gamma \epsilon_0 \sqrt{\Delta l / L}$, where γ is a scaling factor (0.5), Δl is the model resolution
 225 (~56 km in this study), and L represents the range that the observation can reflect, which
 226 depends on the station type (2 km for urban, 4 km for suburban). The total observation error is
 227 then defined as $\epsilon_t = \sqrt{\epsilon_0^2 + \epsilon_r^2}$. Furthermore, the "superobservation" method was applied in
 228 this work to further reduce the influence of representative error (Miyazaki et al., 2017; Tang et
 229 al., 2022):

$$230 \quad \omega_j = 1 / \epsilon_j^2 \quad (\text{Eq. 5})$$

231
$$y_s = \sum_{j=1}^k \omega_j y_j / \sum_{j=1}^k \omega_j \quad (\text{Eq. 6})$$

232
$$1/\varepsilon_s^2 = \sum_{j=1}^k 1/\varepsilon_j^2 \quad (\text{Eq. 7})$$

233 where y_j is O₃ observation of the j th station, ω_j represents the weighting factor of the j th
 234 station, y_s and ε_s are the grid-based O₃ observations and errors (superobservation),
 235 respectively.

236

237 **3. Results and Discussion**

238 **3.1 Surface O₃ by assimilating MEE O₃ observations**

239 We first investigate the effects of surface O₃ observations on single O₃ tracer
 240 assimilations. O₃ at the surface level is formed by precursors mixed in the planetary boundary
 241 layer (PBL). Thus, it may not be accurate to assume that the differences between simulated and
 242 observed surface O₃ concentrations are completely caused by biased O₃ production and loss at
 243 the surface level. Here we adjust O₃ concentrations above the surface level within the PBL
 244 when assimilating surface O₃ observations:

245
$$\Delta O_3^n = \Delta O_3^1 \times \gamma^{n-1} \quad (\text{Eq. 8})$$

246 where ΔO_3^1 is the adjustment at the surface level calculated with Eq. 3; ΔO_3^n is the adjustment
 247 at model level n , which is based on ΔO_3^1 but decays exponentially with the increase in model
 248 level, and the decay speed is adjusted by the γ parameter. As shown in Table 1, three
 249 assimilation experiments (Exp. #5-#7) were conducted to evaluate the effects of the decay
 250 speed: 1) $\gamma = 0$ by assuming that the biased surface O₃ concentrations are completely caused
 251 by biased O₃ production and loss at the surface level; 2) $\gamma = 1$ by assuming full mixing of O₃
 252 biases within the PBL; and 3) $\gamma = 0.8$ by assuming partial mixing of O₃ biases within the
 253 PBL, i.e., the adjustment at the 4th model level is approximately 50% of ΔO_3^1 , and the
 254 adjustment at the 10th model level (close to the top of PBL) is approximately 10% of ΔO_3^1 .

255 As shown in Fig. S2A (see the SI), the assimilated surface MDA8 O₃ concentrations
256 show good agreement by using different γ parameters: 42.3, 41.8 and 42.0 ppb ($\gamma = 0, 0.8$ and
257 1.0) in 2015-2020; there are noticeable discrepancies in the trends of assimilated surface O₃
258 concentrations: 0.80, 1.24 and 1.50 ppb yr⁻¹ ($\gamma = 0, 0.8$ and 1.0) in 2015-2020 (Fig. S2B), and
259 the trends obtained by considering the mixing of O₃ biases ($\gamma = 0.8$ and 1.0) match better with
260 MEE O₃ observations (1.77 ppb yr⁻¹). Fig. S3 (see the SI) further demonstrates tropospheric O₃
261 columns by assimilating MEE O₃ observations in 2015-2020. We find good agreement in the
262 assimilated tropospheric O₃ columns by using different γ parameters, i.e., the mean
263 tropospheric O₃ columns are 38.1, 37.9 and 37.9 DU, and the trends of tropospheric O₃ columns
264 are 0.11, 0.17 and 0.21 ppb yr⁻¹ ($\gamma = 0, 0.8$ and 1.0). Considering the better agreement in the
265 trends of assimilated surface O₃ concentrations ($\gamma = 0.8$ and 1.0) with observations, we finally
266 decide to set $\gamma = 0.8$ as our main assimilation setting by assuming partial mixing of O₃ biases
267 within the PBL.

268 Fig. 4A1-A5 show the annual and seasonal averages of surface MDA8 O₃ observations
269 from MEE stations in 2015-2020. Fig. 4C1-C5 show the annual and seasonal averages of the a
270 posteriori O₃ concentrations by assimilating the MEE O₃ observations. As shown in Fig. 5, the
271 assimilated O₃ concentrations (blue lines) show good agreement with MEE O₃ observations
272 (red lines): the mean surface MDA8 O₃ in 2015-2020 are 43.2, 41.8 and 42.1 ppb (E. China),
273 42.4, 45.6 and 47.6 ppb (North China Plain), 44.6, 45.0 and 44.9 ppb (Yangtze River Delta),
274 45.1, 43.1 and 43.5 ppb (Central China), 45.7, 37.5 and 36.9 ppb (Sichuan Basin), and 43.2,
275 39.2 and 38.3 ppb (Southern China) in the a priori simulations, a posteriori simulations and
276 MEE observations, respectively. It should be noted that Fig. 5A exhibits broadly good
277 agreement between the a priori and a posteriori O₃ concentrations over E. China except for a
278 larger difference in the summer. However, as shown in Fig. 4D1-D5, the good agreements
279 between the a priori and a posteriori O₃ concentrations are caused by the counterbalance of

280 positive biases (i.e., overestimated surface O₃ in the a priori simulations over southern China)
281 and negative biases (i.e., underestimated surface O₃ in the a priori simulations over northern
282 China). The good agreements in Fig. 5A thus cannot represent good performance in the
283 simulations of surface O₃ concentrations.

284 The assimilations exhibit noticeable declines in surface O₃ concentrations over regions
285 #2-5 in June-July, and the declines are underestimated by the a priori simulations (Fig. 5C-F).
286 The inaccurate simulation in June-July thus results in overestimated surface O₃ concentrations
287 in the summer. There is dramatic seasonality in surface O₃ concentrations (Fig. 5): maximum
288 in June in the North China Plain, May and August in the Yangtze River Delta, Central China
289 and Sichuan Basin, and September-October in Southern China. Fig. 4E1-E5 exhibits the effects
290 of seasonal variabilities in background O₃ (Exp. #3) by fixing background O₃ in the spring in
291 the simulations. The fixed background O₃ has limited influences on surface O₃ concentrations,
292 and consequently, the seasonality in surface O₃ concentrations is dominated by local
293 contributions. As we expected, MDA8 O₃ concentrations are higher over areas with higher
294 anthropogenic NO_x emissions, for example, 45.6 and 45.0 ppb in the North China Plain and
295 Yangtze River Delta, respectively, in contrast to 43.1, 37.5 and 39.2 ppb in Central China,
296 Sichuan Basin and Southern China. The influences of regional transport on surface O₃
297 concentrations are limited; for example, O₃ generated within the North China Plain PBL by
298 setting O₃ formation rates within the North China Plain PBL to zero (Exp. #4) are mainly
299 contained within the North China Plain (Fig. 4F1-F5).

300 **3.2 Rapid increasing trends in surface O₃ concentrations**

301 Here we investigate the changes in surface O₃ concentrations from observations and
302 assimilations. As shown in Fig. 6B1-B5, the a priori simulation suggests slightly increasing
303 trends of MDA8 O₃ in 2015-2020: 0.31 (spring), -0.12 (summer), 0.45 (autumn) and 0.40
304 (winter) ppb yr⁻¹, and the relative increasing trends are 0.7 (spring), -0.2 (summer), 1.1

305 (autumn) and 1.4 (winter) % yr⁻¹. The a priori simulation suggests increasing trends of surface
306 O₃ concentrations in the summer over areas with higher local pollution levels, for example,
307 0.68 and 0.63 ppb yr⁻¹ over the North China Plain and Yangtze River Delta, respectively, and
308 decreasing trends of surface O₃ concentrations in the summer over areas with lower local
309 pollution levels, for example, -0.83 and -1.01 ppb yr⁻¹ over the Sichuan Basin and Southern
310 China, respectively. The decreasing trends over areas with lower local pollution levels in the
311 simulations are not surprising, given the decreases in anthropogenic NO_x emissions (Zheng et
312 al., 2018; Jiang et al., 2022) and the reported NO_x-limited O₃ nonlinear chemical regimes in
313 model simulations (Chen et al., 2021; Liu et al., 2021). Furthermore, as shown in Fig. 6D1-D5,
314 the interannual variabilities in background O₃ (Exp. #2) are suggested to result in increases in
315 surface O₃ concentrations in the a priori simulations in 2015-2020 by 0.02 (spring), 0.05
316 (summer), 0.02 (autumn) and 0.00 (winter) ppb yr⁻¹, and the relative contribution is particularly
317 pronounced in the summer.

318 In contrast, the increasing trends in surface O₃ are much stronger in the assimilations. As
319 shown in Table 2.1, our assimilation suggests 1.60 (spring), 1.16 (summer), 1.47 (autumn) and
320 0.80 (winter) ppb yr⁻¹ increases in surface O₃ over E. China in 2015-2020, and the relative
321 increasing trends are 3.4 (spring), 2.2 (summer), 3.7 (autumn) and 2.7 (winter) % yr⁻¹. The
322 annual increasing trend (1.24 ppb yr⁻¹) in the assimilated surface O₃ concentrations is more
323 consistent with the MEE O₃ observations (1.77 ppb yr⁻¹) which are comparable with the
324 reported recent trends in surface O₃ concentrations in China of 1.25-2.0 ppb yr⁻¹
325 (Mousavinezhad et al., 2021; Wei et al., 2022; Wang, W. et al., 2022). The increasing trends
326 are weaker when the modeled surface O₃ concentrations are averaged over E. China (Table
327 2.2) instead of sampling at the locations and times of MEE observations: 0.71 (spring), 0.36
328 (summer), 0.69 (autumn) and 0.54 (winter) ppb yr⁻¹ because most MEE stations are urban sites.
329 Our analysis thus indicates a noticeable underestimation in the increasing trends of surface O₃

330 concentrations in China in the a priori simulations, particularly in the summer, despite the
331 anthropogenic NO_x and VOC emissions having been scaled in the simulations following Jiang
332 et al. (2022).

333 The changes in surface O₃ concentrations have significant regional and seasonal
334 discrepancies. As shown in Tables S1-S5 (see the SI), our assimilations demonstrate strong
335 increasing trends in surface O₃ concentrations in 2015-2020 in spring (1.94 ppb yr⁻¹ or 3.8%
336 yr⁻¹) and summer (2.52 ppb yr⁻¹ or 4.0% yr⁻¹) over the North China Plain; in spring (2.21 ppb
337 yr⁻¹ or 4.4% yr⁻¹) and autumn (1.84 ppb yr⁻¹ or 4.1% yr⁻¹) over the Yangtze River Delta; in
338 spring (2.07 ppb yr⁻¹ or 4.3% yr⁻¹) and autumn (2.09 ppb yr⁻¹ or 4.7% yr⁻¹) over Central China;
339 in spring (1.69 ppb yr⁻¹ or 3.8% yr⁻¹) over the Sichuan Basin; and in autumn (2.21 ppb yr⁻¹ or
340 4.9% yr⁻¹) over Southern China. While surface O₃ concentrations are higher over areas with
341 higher anthropogenic NO_x emissions, the increasing trends in surface O₃ concentrations over
342 Central China and Southern China are comparable with those in the North China Plain and
343 Yangtze River Delta. Our analysis advises more attention to O₃ pollution in spring and autumn
344 over areas with lower anthropogenic NO_x emissions because of the rapid increases in surface
345 O₃ concentrations.

346 **3.3 Tropospheric O₃ columns by assimilating OMI O₃ observations**

347 Fig. 7A1-A5 show the annual and seasonal averages of tropospheric OMI O₃ columns in
348 2015-2020. OMI is sensitive to O₃ at different vertical levels (Huang et al., 2017; Fu et al.,
349 2018), and thus, the standard KF algorithm (Eq. 3) was employed to adjust tropospheric O₃
350 vertical profiles with the application of OMI O₃ averaging kernels. Fig. 7C1-C5 show the
351 annual and seasonal averages of the a posteriori tropospheric O₃ columns by assimilating OMI
352 O₃ observations. The assimilated tropospheric O₃ columns show good agreement with OMI O₃
353 observations: the mean tropospheric O₃ columns in 2015-2020 (Table 2.3) are 37.1 DU in the
354 a priori simulations and 37.9 and 38.0 DU in the a posteriori simulation and OMI observations,

355 respectively. The discrepancies between the a priori and a posteriori simulations in tropospheric
356 O₃ columns (Fig. 7) are smaller than those in surface O₃ concentrations (Fig. 4). A better
357 simulation capability in tropospheric column O₃ is expected because model simulation with
358 0.5°×0.625° horizontal resolution may not be enough to accurately resolve O₃ nonlinear
359 chemical regimes over urban surface stations.

360 The above assimilated tropospheric O₃ columns (Exp. #8) are driven by optimized O₃
361 background conditions provided by global assimilations of OMI O₃ as well as row-isolated
362 OMI data by using across-track positions between 4-11. Fig. 7E1-E5 exhibits the effects of
363 optimization on regional O₃ background conditions. The mean assimilated tropospheric O₃
364 column driven by the original O₃ background conditions is 37.6 DU (Exp. #9), which is slightly
365 lower than the 37.9 DU in the main assimilation (Exp. #8). The usage of original O₃ background
366 conditions can result in overestimations over southern China in the spring and winter, and
367 underestimations over northern China in the spring and summer (Fig. 7E1-E5). Fig. 7F1-F5
368 further exhibits the effects of the usage of row-isolated data. The mean assimilated tropospheric
369 O₃ column by assimilating OMI O₃ observations at across-track positions 4-27 is 37.7 DU (Exp.
370 #10), which is slightly lower than the 37.9 DU in the main assimilation (Exp. #8). The
371 underestimations in the assimilated tropospheric O₃ columns are particularly significant in the
372 spring and summer (Fig. 7F2-F3).

373 As shown in Fig. 8, the trends of tropospheric O₃ columns in 2015-2020 (Table 2.3) are
374 0.02 DU yr⁻¹ in the a priori simulations and -0.17 and -0.30 DU yr⁻¹ in the a posteriori
375 simulation and OMI observations, respectively. In contrast to the wide distributions of
376 increasing trends of O₃ at the surface level (Fig. 6), both OMI O₃ observations (-0.30 DU yr⁻¹)
377 and the OMI-based assimilations (-0.17 DU yr⁻¹) suggest decreasing trends in tropospheric O₃
378 columns over E. Asia in 2015-2020 (Fig. 8). The decreasing trends are stronger in the summer
379 and weaker in the spring. Furthermore, the usage of original O₃ background conditions can

380 result in overestimated trend by approximately 0.08 DU yr^{-1} (Fig. 8D1); and the assimilation
381 of OMI O_3 observations at across-track positions 4-27 can result in a similar overestimated
382 trend, by approximately 0.08 DU yr^{-1} (Fig. 8E1). These discrepancies demonstrate the
383 importance of optimized usages of regional O_3 background conditions and OMI O_3
384 observations in the assimilations.

385 **3.4 Changes in tropospheric O_3 columns**

386 The trends shown in Fig. 8 may not represent the actual tropospheric O_3 changes well
387 because the convolution of OMI O_3 averaging kernels on the output O_3 profiles can affect the
388 weights of the derived tropospheric columns to O_3 at different vertical levels. Consequently,
389 Fig. 9 shows the annual and seasonal averages of tropospheric O_3 columns in which the output
390 O_3 profiles are not convolved with OMI retrieval averaging kernels so that they can better
391 represent the actual atmospheric O_3 state. The assimilated tropospheric O_3 columns are 37.9
392 and 38.8 DU (E. China), 42.9 and 43.7 DU (North China Plain), 47.5 and 48.1 DU (Yangtze
393 River Delta), 47.4 and 48.1 DU (Central China), 43.8 and 44.6 DU (Sichuan Basin), and 39.6
394 and 40.6 DU (Southern China) in 2015-2020 by assimilating MEE and OMI O_3 observations,
395 respectively.

396 In contrast to the higher surface MDA8 O_3 concentrations over areas with higher
397 anthropogenic NO_x emissions, tropospheric O_3 columns over Central China and the Sichuan
398 Basin are even higher than those over the highly polluted North China Plain. In addition,
399 tropospheric O_3 columns obtained by assimilating MEE surface O_3 observations are lower than
400 those obtained by assimilating OMI O_3 observations, and their difference is larger in the
401 summer and smaller in the winter. As shown in Fig. S4 (see the SI), the impacts of different
402 surface and satellite O_3 observations on the assimilated O_3 vertical profiles are limited. The
403 assimilation of MEE surface O_3 observations leads to decreases in O_3 concentrations in the
404 lower troposphere from the surface to 600 hPa levels over the Sichuan Basin and Southern

405 China; the assimilation of OMI O₃ observations leads to enhancement in O₃ concentrations in
406 the middle and upper troposphere over the highly polluted North China Plain.

407 The assimilated tropospheric O₃ columns are maximum in June-July over the highly
408 polluted North China Plain and March-May over other lower polluted regions (Fig. S5, see the
409 SI). Fig. 9E1-E5 exhibit the effects of seasonal variabilities in background O₃ (Exp. #3). The
410 fixed background O₃ in the spring can result in dramatic increases in tropospheric O₃ columns
411 by 14.3 (summer), 15.1 (autumn) and 4.8 (winter) DU over E. China. Fig. 9F1-F5 further
412 exhibit the effects of O₃ formation within the North China Plain PBL (Exp. #4) on tropospheric
413 O₃ columns, which are 5.4 (spring), 8.1 (summer), 3.6 (autumn) and 1.3 (winter) DU over the
414 North China Plain. In addition, as shown in Fig. S6 (see the SI), there is a larger enhancement
415 in O₃ production rates in the free troposphere (600-300 hPa) over the North China Plain in the
416 summer than in other lower polluted regions. Consequently, the spring maximum in
417 tropospheric O₃ columns over lower polluted regions is caused by the enhanced background O₃
418 (Fig. 9E1-E5), and the summer maximum in tropospheric O₃ columns over the highly polluted
419 North China Plain is caused by the local contributions from enhanced O₃ formation within the
420 North China Plain PBL (Fig. 9F1-F5) and free troposphere (Fig. S6).

421 As shown in Fig. 10A1-A5, the trends of tropospheric O₃ columns in the a priori
422 simulations in 2015-2020 are -0.02 (spring), 0.02 (summer), 0.29 (autumn) and 0.09 (winter)
423 DU yr⁻¹ over E. China. The interannual variability in background O₃ (Fig. 10D1-D5, Exp. #2)
424 is suggested to have important contributions to the trends of tropospheric O₃ columns by 0.09
425 (spring), -0.11 (summer), -0.10 (autumn) and -0.08 (winter) DU yr⁻¹. The trends of assimilated
426 tropospheric O₃ columns are 0.17 and -0.10 DU yr⁻¹ (E. China), which are comparable with the
427 reported recent trend in free tropospheric O₃ concentrations over China by -0.14 DU yr⁻¹
428 (Dufour et al., 2021), and are 0.47 and 0.12 DU yr⁻¹ (North China Plain), 0.45 and 0.13 DU yr⁻¹
429 (Yangtze River Delta), 0.32 and -0.06 DU yr⁻¹ (Central China), 0.03 and -0.29 DU yr⁻¹

430 (Sichuan Basin), and 0.06 and -0.25 DU yr⁻¹ (Southern China) by assimilating MEE and OMI
431 O₃ observations, respectively.

432 The stronger increasing trends in tropospheric O₃ columns over the highly polluted North
433 China Plain (Fig. 10A1) are suggested to be caused by larger local contributions because of
434 relatively uniform influences from interannual variability in background O₃ (Fig. 10D1).
435 Higher positive trends by assimilating MEE observations are expected, given the increasing
436 trends in surface O₃ concentrations (1.77 ppb yr⁻¹) and decreasing trends in OMI O₃
437 concentrations (-0.30 DU yr⁻¹) over E. China. Furthermore, it should be noted that while the
438 Yangtze River Delta is defined as a highly polluted region in our analysis, its area is much
439 smaller than that of the North China Plain (Fig. 1); thus, the impact of local contributions on
440 tropospheric O₃ columns over the Yangtze River Delta is not as strong as that over the North
441 China Plain.

442 **4. Conclusion**

443 A single O₃ tracer (tagged-O₃) mode was developed in this work to build the capability
444 of the GEOS-Chem model for rapid simulations of tropospheric O₃. The single O₃ tracer
445 simulation demonstrates consistency with the GEOS-Chem full chemistry simulation. In
446 contrast, the O_x concentrations provided by the tagged-O_x mode are higher than the O₃
447 concentrations by approximately 6 ppb, and the relative difference can reach 40% in the winter.
448 The computational costs of the single O₃ tracer mode are reduced by approximately 91-94%
449 with respect to the full chemistry mode. For example, the computational costs (hours of wall
450 time per simulation year) are 57.5 and 5.2 hours at the global scale (4°×5°) and 80.2 and 4.5
451 hours within the nested China domain (0.5°×0.625°) by full chemistry and single O₃ tracer
452 simulations, respectively. The low computational costs allow us to design and perform different
453 experiments much more efficiently. As shown in Table 1, 10 different simulation and
454 assimilation experiments are performed in this work to analyze the impacts of background and

455 local contributions to surface and free tropospheric O₃ changes over E. China in 2015-2020,
456 which requires 4812 hours (wall time) with the full chemistry simulation but only 270 hours
457 (wall time) with the single O₃ tracer simulation.

458 The assimilated surface O₃ concentrations demonstrate good agreement with surface O₃
459 observations: 43.2, 41.8 and 42.1 ppb over E. China in a priori and a posteriori simulations and
460 observations, respectively. We find noticeable biases in modeled surface O₃ concentrations, for
461 example, overestimated surface O₃ over southern China and underestimated surface O₃ over
462 northern China. The assimilations indicate rapidly increasing trends in surface O₃
463 concentrations by 1.60 (spring), 1.16 (summer), 1.47 (autumn) and 0.80 (winter) ppb yr⁻¹ over
464 E. China in 2015-2020, and the increasing trends are underestimated by the a priori simulations.
465 While surface O₃ concentrations are higher over areas with higher anthropogenic NO_x
466 emissions, the increasing trends in surface O₃ concentrations over Central China and Southern
467 China are comparable with those in the North China Plain and Yangtze River Delta. Our
468 analysis thus advises more attention to O₃ pollution in spring and autumn over areas with lower
469 anthropogenic NO_x emissions because of the rapid increases in surface O₃ concentrations. The
470 seasonality in surface O₃ concentrations is dominated by local contributions; however, the
471 interannual variabilities in background O₃ have noticeable contributions to the increasing
472 trends in surface O₃ particularly in the summer in the a priori simulations.

473 The assimilated tropospheric O₃ columns demonstrate good agreement with OMI
474 observations: 37.1, 37.9 and 38.0 DU over E. China in a priori and a posteriori simulations
475 (convolved with OMI retrieval averaging kernels) and OMI observations, respectively. The
476 trends of assimilated tropospheric O₃ columns in 2015-2020 over E. China are 0.09 and -0.17
477 (spring), 0.17 and -0.22 (summer), 0.38 and 0.04 (autumn), and 0.12 and -0.02 (winter) by
478 assimilating MEE and OMI O₃ observations, respectively. The large discrepancy by
479 assimilating surface and satellite observations indicates the possible uncertainties in the derived

480 free tropospheric O₃ changes. The usage of optimized O₃ background conditions and row-
481 isolated OMI data is important to produce more reliable results, for example, the usage of
482 original O₃ background conditions can result in an overestimated trend by approximately 0.08
483 DU yr⁻¹ in 2015-2020.

484 We find stronger increasing trends in tropospheric O₃ columns over highly polluted areas
485 due to the larger local contributions, for example, 0.47 and 0.12 DU yr⁻¹ (North China Plain)
486 in contrast to 0.03 and -0.29 DU yr⁻¹ (Sichuan Basin) and 0.06 and -0.25 DU yr⁻¹ (Southern
487 China) by assimilating MEE and OMI O₃ observations, respectively. The spring maximum in
488 tropospheric O₃ columns over lower polluted regions is caused by the enhanced background
489 O₃, and the summer maximum in tropospheric O₃ columns over the highly polluted North China
490 Plain is caused by enhanced local O₃ formation. The interannual variabilities in background O₃
491 have important contributions to the trends in tropospheric O₃ columns; for example, the trends
492 of tropospheric O₃ columns in 2015-2020 are -0.02 (spring), 0.02 (summer), 0.29 (autumn) and
493 0.09 (winter) DU yr⁻¹ over E. China, and the contributions from interannual variability in
494 background O₃ are 0.09 (spring), -0.11 (summer), -0.10 (autumn) and -0.08 (winter) DU yr⁻¹ in
495 the a priori simulations. Assimilations of both surface and satellite observations, as shown in
496 this work, can provide useful information to better describe the changes in surface and free
497 tropospheric O₃.

498

499 **Code and data availability:** The MEE O₃ data can be downloaded from
500 <https://quotsoft.net/air/>. The AQS and AirBase surface O₃ data can be downloaded from
501 <https://www.eea.europa.eu/data-and-maps/data/aqereporting-8> and
502 https://aqs.epa.gov/aqsweb/airdata/download_files.html#Row. The OMI PROFOZ product
503 can be acquired at
504 <https://avdc.gsfc.nasa.gov/pub/data/satellite/Aura/OMI/V03/L2/OMPFOZ/>. The GEOS-

505 Chem model (version 12.8.1) can be downloaded from [http://wiki.seas.harvard.edu/geos-](http://wiki.seas.harvard.edu/geos-chem/index.php/GEOS-Chem_12#12.8.1)
506 [chem/index.php/GEOS-Chem_12#12.8.1](http://wiki.seas.harvard.edu/geos-chem/index.php/GEOS-Chem_12#12.8.1). The KPP module for tagged-O₃ simulations can be
507 downloaded from <https://doi.org/10.5281/zenodo.7545944>.

508

509 **Author Contributions:** Z.J. designed the research. R.Z. developed the model code and
510 performed the research. Z.J. and R.Z. wrote the manuscript. X.L. provided instruction for the
511 usage of OMI data. All authors contributed to discussions and editing the manuscript.

512

513 **Competing interests:** The contact author has declared that neither they nor their co-authors
514 have any competing interests.

515

516 **Acknowledgments:** We thank the China Ministry of Ecology and Environment (MEE), the
517 United States Environmental Protection Agency and the European Environmental Agency for
518 providing the surface O₃ measurements. The numerical calculations in this paper have been
519 done on the supercomputing system in the Supercomputing Center of University of Science
520 and Technology of China. This work was supported by the Hundred Talents Program of
521 Chinese Academy of Science and National Natural Science Foundation of China (42277082,
522 41721002).

523 **Table and Figures**

524 **Table 1.** Single O₃ tracer simulation and assimilation experiments (Exp.) conducted in this
525 work. Exp. #1: the main a priori simulation; Exp. #2: O₃ boundary conditions and stratospheric
526 O₃ concentrations are fixed in 2015; Exp. #3: O₃ boundary conditions and stratospheric O₃
527 concentrations are fixed in the spring; Exp. #4: O₃ formation rates within the North China Plain
528 PBL are set to zero; Exp. #5: the main assimilation by assimilating MEE surface O₃
529 observations with $\gamma = 0.8$; Exp. #6: only surface O₃ concentrations are adjusted ($\gamma = 0$); Exp.
530 #7: full mixing of O₃ biases within the PBL ($\gamma = 1.0$); Exp. #8: the main assimilation by

531 assimilating OMI O₃ observations; Exp. #9: O₃ boundary conditions are not optimized; Exp.
532 #10: assimilating OMI O₃ observations at across-track positions 4-27.

533

534 **Table 2.** Averages (with units ppb or DU) and trends (with units ppb yr⁻¹ or DU yr⁻¹) of surface
535 and tropospheric column O₃ concentrations in 2015-2020 over E. China from observations
536 (MEE and OMI) and a priori (Exp. #1) and a posteriori (KF) simulations (Exp. #5 and #8).
537 T2.1): the modeled surface O₃ is sampled at the locations and times of MEE surface O₃
538 observations; T2.2): the modeled surface O₃ is averaged over E. China (land only); T2.3): the
539 output O₃ profiles from the a priori and a posteriori simulations are convolved with OMI O₃
540 averaging kernels; T2.4): the output O₃ profiles are NOT convolved with OMI O₃ averaging
541 kernels. The uncertainties in the averages are calculated using the bootstrapping method. The
542 trends and uncertainties in the trends are calculated using the linear fitting of averages by using
543 the least squares method (see details in the SI).

544

545 **Fig. 1.** (A) Anthropogenic NO_x emissions over E. China in 2015; (B) Region definitions for
546 the North China Plain (#1), Yangtze River Delta (#2), Central China (#3), Sichuan Basin (#4)
547 and Southern China (#5). The different colors (red, gray and green) represent grids with high
548 (highest 15%), medium (15-50%) and low (lowest 50%) anthropogenic NO_x emissions.
549 Regions #1 and #2 are defined as highly polluted (HP) regions by excluding grids with low and
550 medium anthropogenic NO_x emissions.

585 **Fig. 8.** Trends of tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from
586 (A1-A5) OMI observations; (B1-B5) GEOS-Chem a priori simulation (Exp. #1); (C1-C5)
587 GEOS-Chem a posteriori simulation by assimilating OMI O₃ observations (Exp. #8). (D1-D5)
588 Effects of optimization on regional O₃ background conditions (Exp. #9 minus #8); (E1-E5)
589 Effects of the usage of row-isolated data (Exp. #10 minus #8). The output O₃ profiles are
590 convolved with OMI averaging kernels.

591

592 **Fig. 9.** Tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A1-A5)
593 GEOS-Chem a priori simulation (Exp. #1); (B1-B5) Assimilations of MEE surface O₃
594 observations (Exp. #5); (C1-C5) Assimilations of OMI O₃ observations (Exp. #8). (D1-D5)
595 Difference in tropospheric O₃ columns calculated by OMI-based assimilations minus MEE-
596 based assimilations (Exp. #8 minus #5). (E1-E5) Effects of seasonal variabilities in background
597 O₃ (Exp. #3 minus #1); (F1-F5) Effects of O₃ formation within the North China Plain PBL
598 (Exp. #4 minus #1). The output O₃ profiles are NOT convolved with OMI averaging kernels.

599

600 **Fig. 10.** Trends of tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from
601 (A1-A5) GEOS-Chem a priori simulation (Exp. #1); (B1-B5) Assimilations of MEE surface
602 O₃ observations (Exp. #5); (C1-C5) Assimilations of OMI O₃ observations (Exp. #8). (D1-D5)
603 Effects of interannual variabilities in background O₃ (Exp. #1 minus #2). The output O₃ profiles
604 are NOT convolved with OMI averaging kernels.

Table 1. Single O₃ tracer simulation and assimilation experiments (Exp.) conducted in this work. Exp. #1: the main a priori simulation; Exp. #2: O₃ boundary conditions and stratospheric O₃ concentrations are fixed in 2015; Exp. #3: O₃ boundary conditions and stratospheric O₃ concentrations are fixed in the spring; Exp. #4: O₃ formation rates within the North China Plain PBL are set to zero; Exp. #5: the main assimilation by assimilating MEE surface O₃ observations with $\gamma = 0.8$; Exp. #6: only surface O₃ concentrations are adjusted ($\gamma = 0$); Exp. #7: full mixing of O₃ biases within the PBL ($\gamma = 1.0$); Exp. #8: the main assimilation by assimilating OMI O₃ observations; Exp. #9: O₃ boundary conditions are not optimized; Exp. #10: assimilating OMI O₃ observations at across-track positions 4-27.

Table 2. Averages (with units ppb or DU) and trends (with units ppb yr⁻¹ or DU yr⁻¹) of surface and tropospheric column O₃ concentrations in 2015-2020 over E. China from observations (MEE and OMI) and a priori (Exp. #1) and a posteriori (KF) simulations (Exp. #5 and #8). T2.1): the modeled surface O₃ is sampled at the locations and times of MEE surface O₃ observations; T2.2): the modeled surface O₃ is averaged over E. China (land only); T2.3): the output O₃ profiles from the a priori and a posteriori simulations are convolved with OMI O₃ averaging kernels; T2.4): the output O₃ profiles are NOT convolved with OMI O₃ averaging kernels. The uncertainties in the averages are calculated using the bootstrapping method. The trends and uncertainties in the trends are calculated using the linear fitting of averages by using the least squares method (see details in the SI).

Fig. 1. (A) Anthropogenic NO_x emissions over E. China in 2015; (B) Region definitions for the North China Plain (#1), Yangtze River Delta (#2), Central China (#3), Sichuan Basin (#4) and Southern China (#5). The different colors (red, gray and green) represent grids with high (highest 15%), medium (15-50%) and low (lowest 50%) anthropogenic NO_x emissions. Regions #1 and #2 are defined as highly polluted (HP) regions by excluding grids with low and medium anthropogenic NO_x emissions.

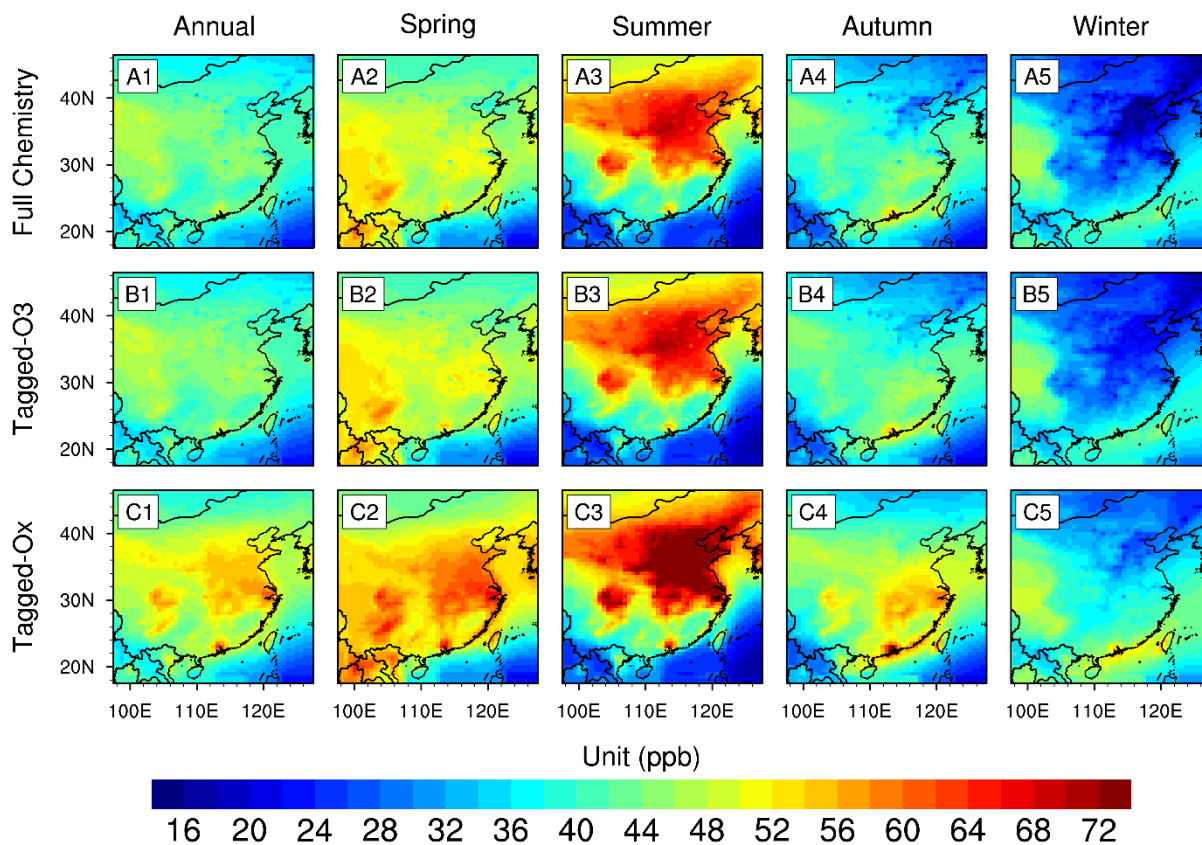

Fig. 2. Surface MDA8 O₃ in 2015-2020 (annual and seasonal averages) simulated by GEOS-Chem model with (A1-A5) full chemistry mode; (B1-B5) single O₃ tracer (tagged-O₃) mode; and (C1-C5) tagged-O_x mode. The 8-hour range of surface O_x is selected according to the time range of MDA8 O₃.

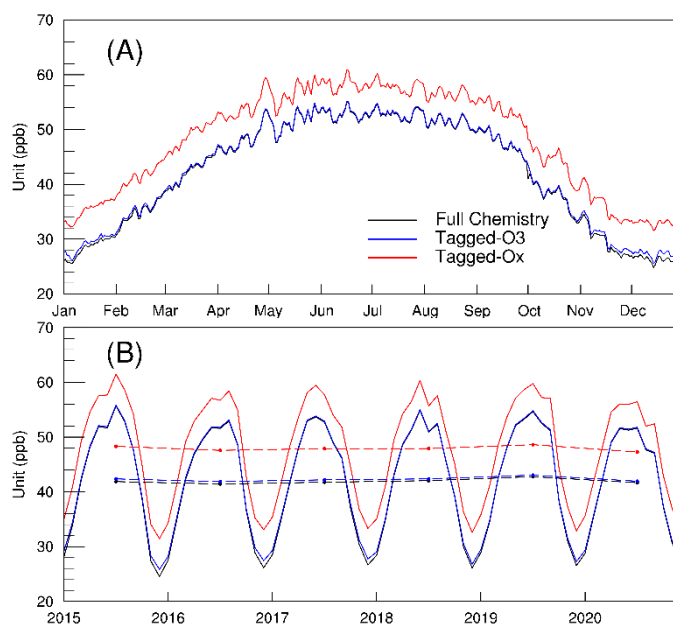

Fig. 3. (A) Daily averages of surface MDA8 O₃ over E. China in 2015-2020 from GEOS-Chem full chemistry (black), single O₃ tracer (tagged-O₃) (blue) and tagged-O_x (red) simulations; (B) Monthly averages of MDA8 O₃. The dashed lines in panel B are annual averages.

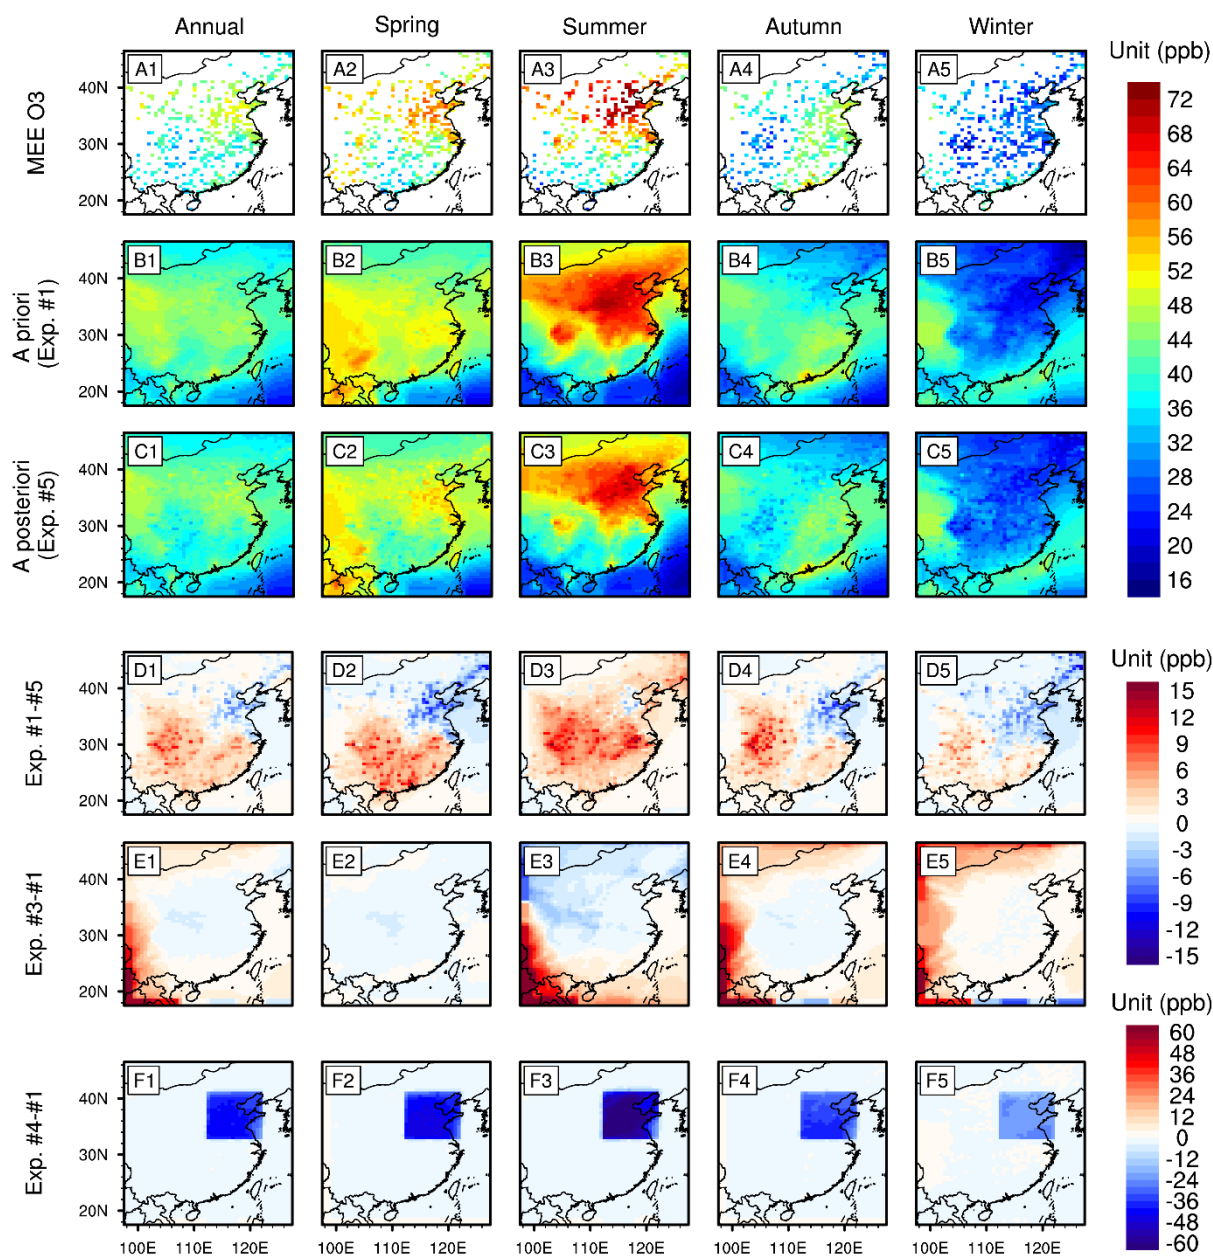

Fig. 4. Surface MDA8 O₃ in 2015-2020 (annual and seasonal averages) from (A1-A5) MEE stations; (B1-B5) GEOS-Chem a priori simulation (Exp. #1); (C1-C5) GEOS-Chem a posteriori simulation by assimilating MEE O₃ observations (Exp. #5); (D1-D5) Bias in the a priori simulations (Exp. #1 minus #5). (E1-E5) Effects of seasonal variabilities in background O₃ (Exp. #3 minus #1); (F1-F5) Effects of O₃ formation within the North China Plain PBL (Exp. #4 minus #1).

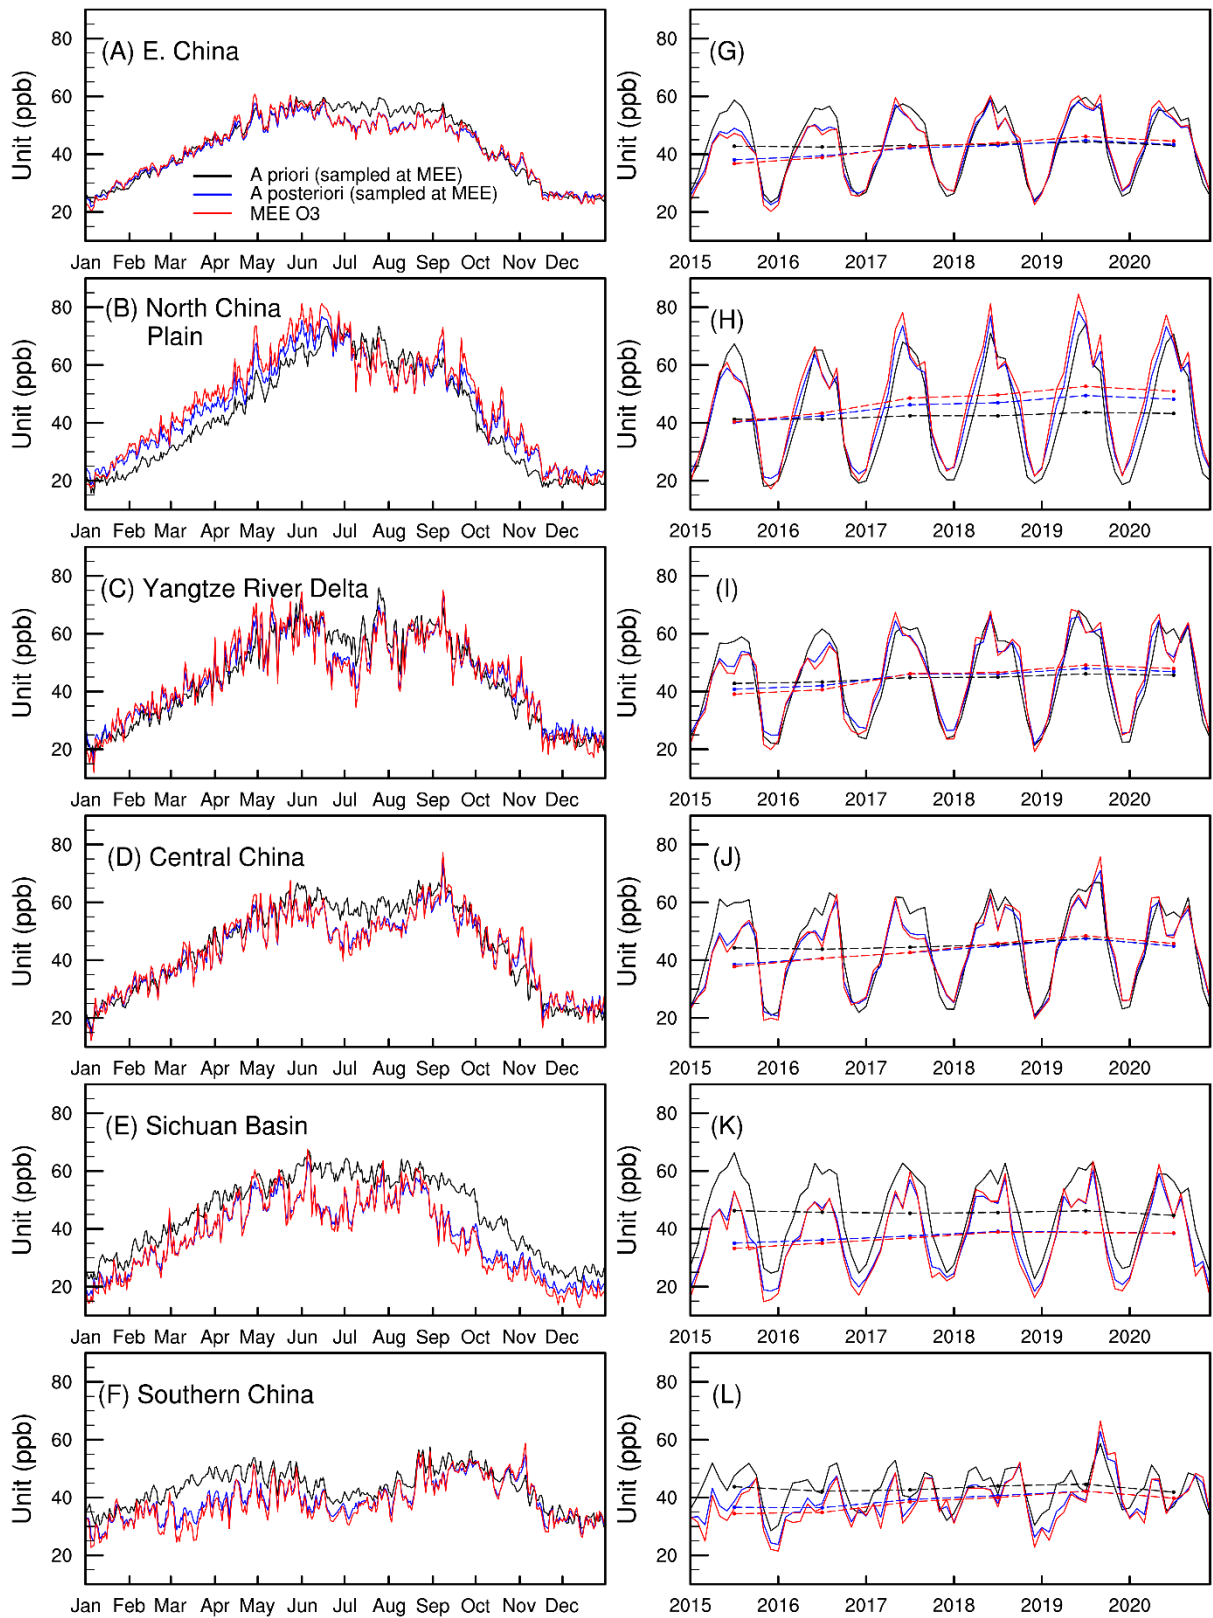

Fig. 5. (A-F) Daily averages of surface MDA8 O₃ in 2015-2020 from MEE stations (red) and GEOS-Chem a priori (black, Exp. #1) and a posteriori (blue, Exp. #5) simulations by assimilating MEE O₃ observations. (G-L) Monthly averages of MDA8 O₃. The dashed lines in panels G-L are annual averages.

Fig. 6. Trends of surface MDA8 O₃ in 2015-2020 (annual and seasonal averages) from (A1-A5) MEE stations; (B1-B5) GEOS-Chem a priori simulation (Exp. #1); (C1-C5) GEOS-Chem a posteriori simulation by assimilating MEE O₃ observations (Exp. #5). (D1-D5) Effects of interannual variabilities in background O₃ (Exp. #1 minus #2).

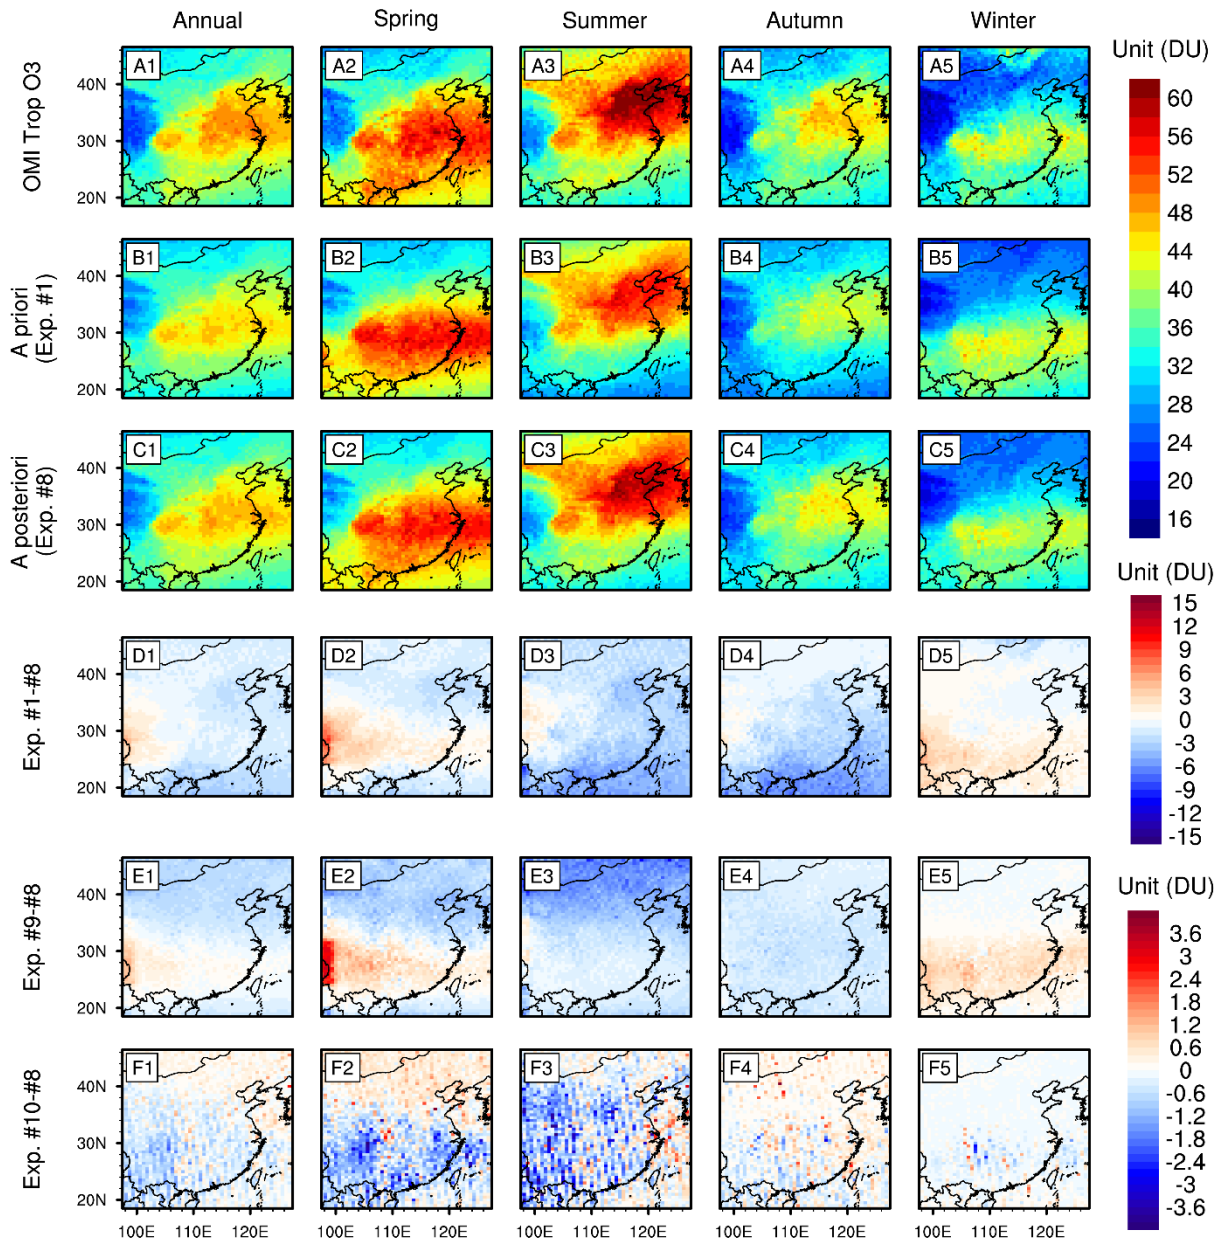

Fig. 7. Tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A1-A5) OMI observations; (B1-B5) GEOS-Chem a priori simulation (Exp. #1); (C1-C5) GEOS-Chem a posteriori simulation by assimilating OMI O₃ observations (Exp. #8). (D1-D5) Bias in the a priori simulations (Exp. #1 minus #8). (E1-E5) Effects of optimization on regional O₃ background conditions (Exp. #9 minus #8); (F1-F5) Effects of the usage of row-isolated data (Exp. #10 minus #8). The output O₃ profiles are convolved with OMI averaging kernels.

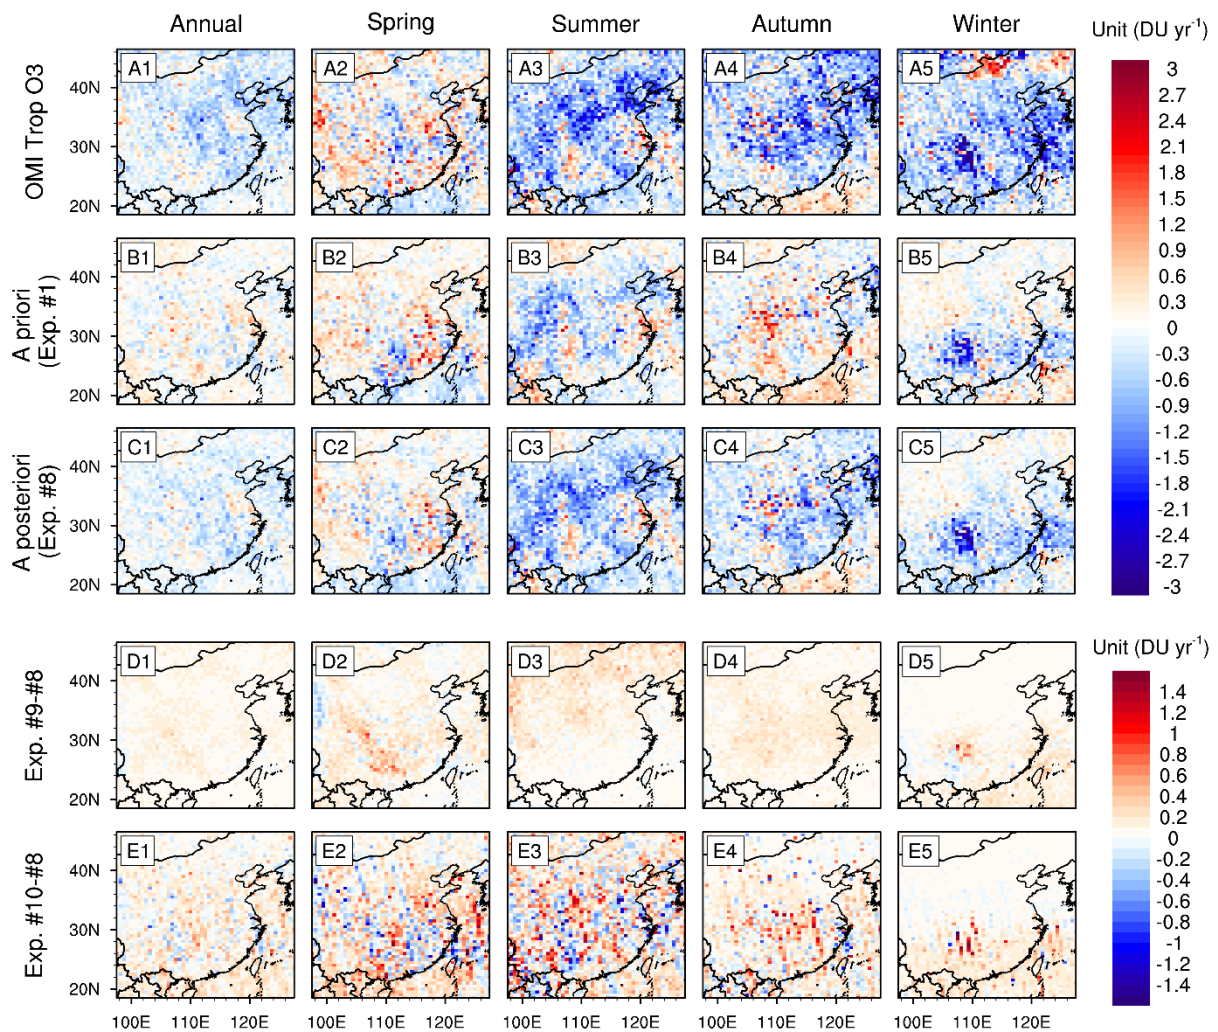

Fig. 8. Trends of tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A1-A5) OMI observations; (B1-B5) GEOS-Chem a priori simulation (Exp. #1); (C1-C5) GEOS-Chem a posteriori simulation by assimilating OMI O₃ observations (Exp. #8). (D1-D5) Effects of optimization on regional O₃ background conditions (Exp. #9 minus #8); (E1-E5) Effects of the usage of row-isolated data (Exp. #10 minus #8). The output O₃ profiles are convolved with OMI averaging kernels.

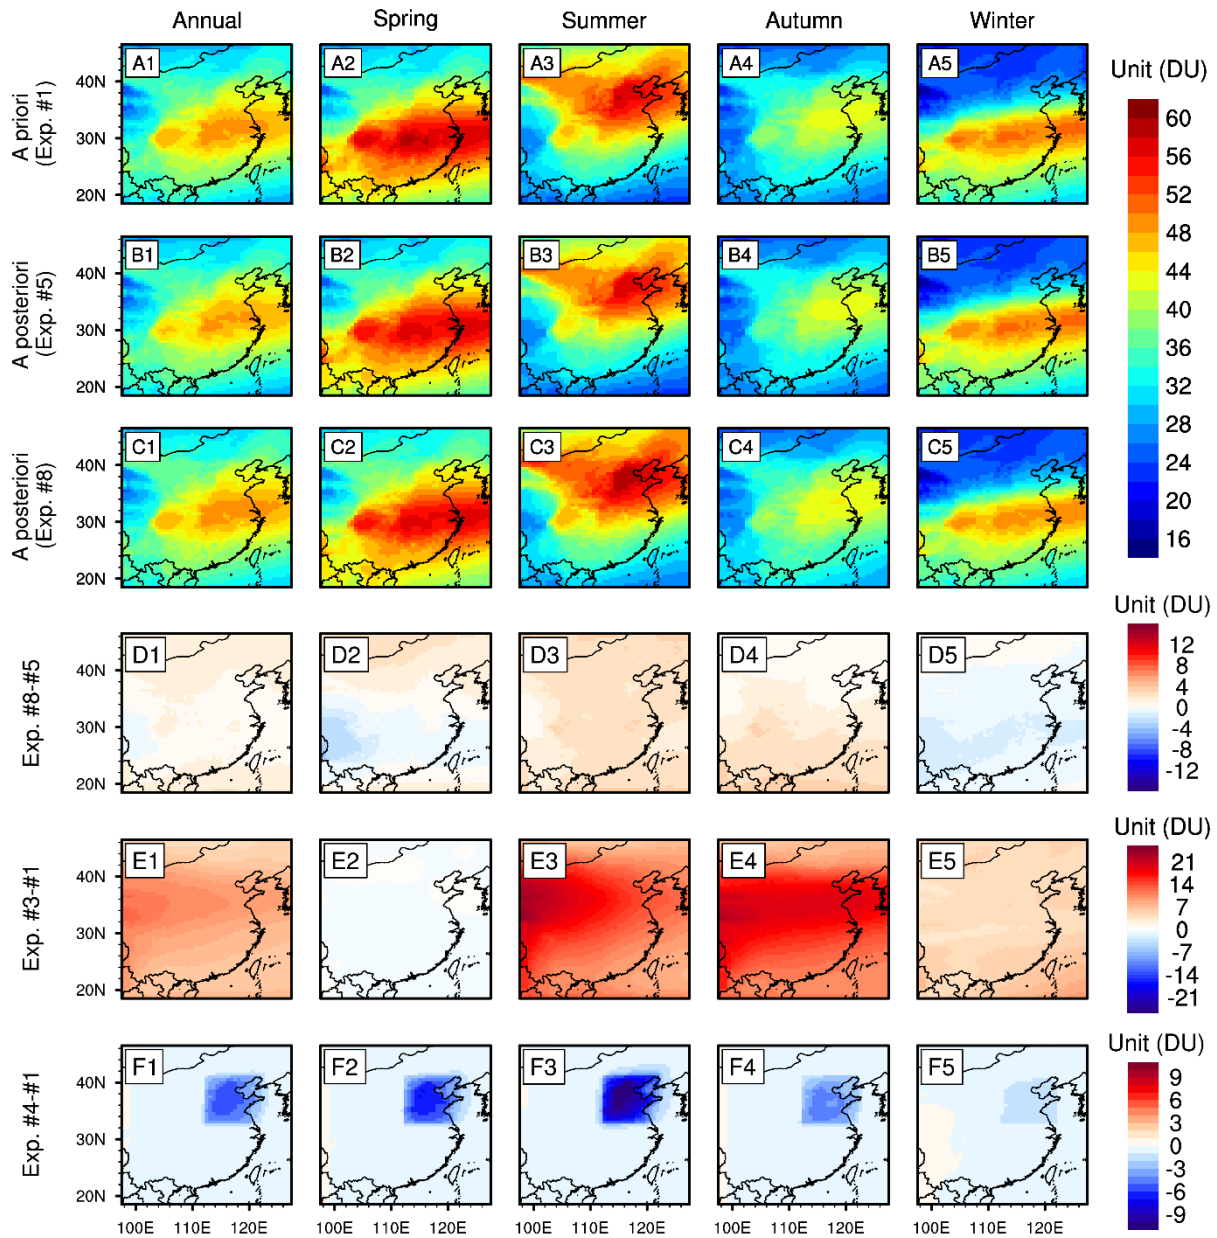

Fig. 9. Tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A1-A5) GEOS-Chem a priori simulation (Exp. #1); (B1-B5) Assimilations of MEE surface O₃ observations (Exp. #5); (C1-C5) Assimilations of OMI O₃ observations (Exp. #8). (D1-D5) Difference in tropospheric O₃ columns calculated by OMI-based assimilations minus MEE-based assimilations (Exp. #8 minus #5). (E1-E5) Effects of seasonal variabilities in background O₃ (Exp. #3 minus #1); (F1-F5) Effects of O₃ formation within the North China Plain PBL (Exp. #4 minus #1). The output O₃ profiles are NOT convolved with OMI averaging kernels.

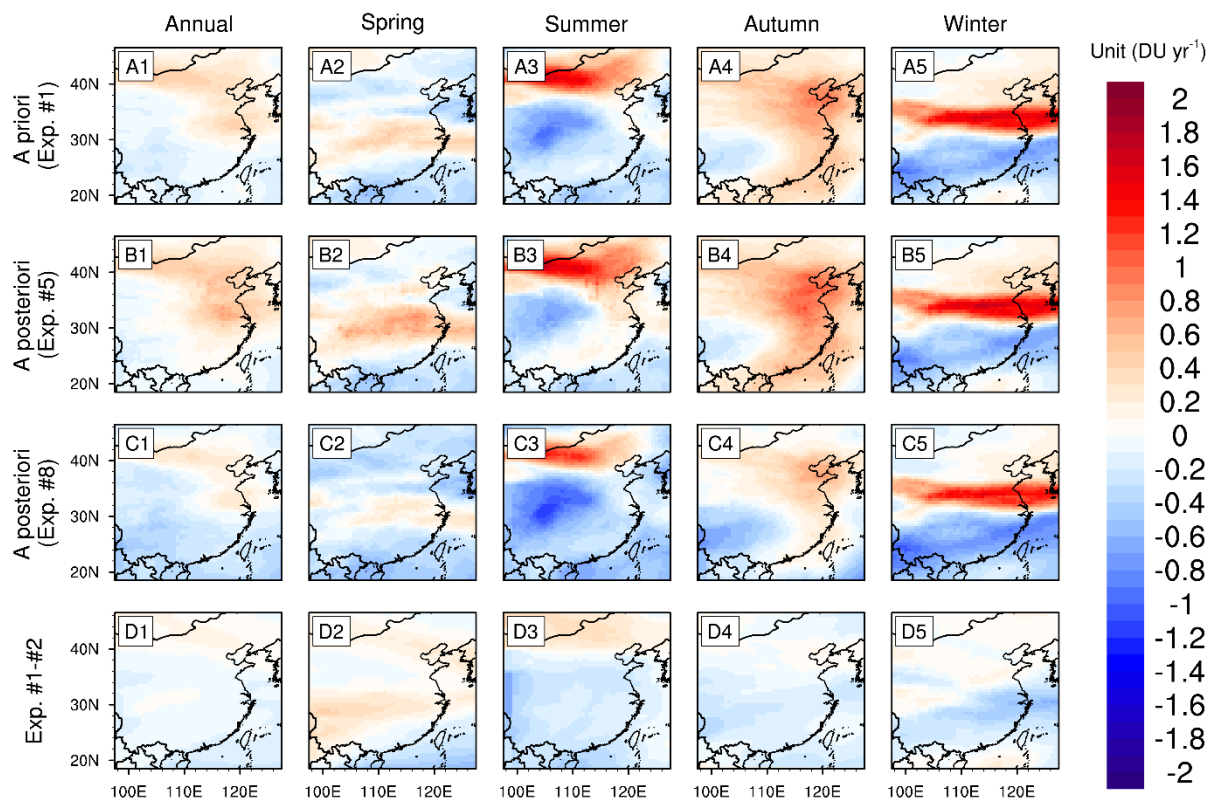

Fig. 10. Trends of tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A1-A5) GEOS-Chem a priori simulation (Exp. #1); (B1-B5) Assimilations of MEE surface O₃ observations (Exp. #5); (C1-C5) Assimilations of OMI O₃ observations (Exp. #8). (D1-D5) Effects of interannual variabilities in background O₃ (Exp. #1 minus #2). The output O₃ profiles are NOT convolved with OMI averaging kernels.
