13 **Abstract**

14 The high computational cost of chemical transport models (CTMs) is a potential bottleneck for
15 the rapid assimilation of ozone (O₃) observations. Here we developed a single tracer tagged-
16 O₃ mode to build the capability of the GEOS-Chem model for rapid simulation of tropospheric
17 O₃. The tagged-O₃ mode demonstrates high consistency with GEOS-Chem full-chemistry
18 simulation and dramatic reductions in computational costs by approximately 91-94%. The
19 tagged-O₃ simulation was combined with China Ministry of Ecology and Environment (MEE)
20 and Ozone Monitoring Instrument (OMI) O₃ observations to investigate the changes in
21 tropospheric O₃ over E. Asia in 2015-2020. The assimilated O₃ concentrations demonstrate
22 good agreement with O₃ observations: surface O₃ concentrations are 42.9, 41.8 and 42.1 ppb;
23 and tropospheric O₃ columns are 37.1, 37.9 and 38.0 DU in the simulations, assimilations and
24 observations, respectively. The assimilations indicate rapid increases in surface O₃ by 1.60
25 (spring), 1.16 (summer), 1.47 (autumn) and 0.80 (winter) ppb yr⁻¹ over E. China in 2015-2020,
26 and the increasing trends are underestimated by the a priori simulations. More attention is thus
27 suggested to the rapid increases in O₃ pollution in spring and autumn. Furthermore, we find
28 stronger increases in tropospheric O₃ columns over highly polluted areas, which may reflect
29 the larger contributions of local emissions. The large discrepancy in the trends in tropospheric
30 O₃ columns by assimilating surface and satellite observations further indicates the possible
31 uncertainties in the derived free tropospheric O₃ changes. The rapid O₃ assimilation capability

32 is a useful tool for the extension and interpretation of atmospheric O₃ observations.

33

34 **1. Introduction**

35 Tropospheric ozone (O₃) is an important pollutant with significant adverse effects on
36 human health and crop growth (Zhang et al., 2021; Li et al., 2022). Tropospheric O₃ is produced
37 when volatile organic compounds (VOC) and carbon monoxide (CO) are photochemically
38 oxidized in the presence of nitrogen oxides (NO_x). Chemical transport models (CTMs) are
39 widely used to simulate tropospheric O₃ variabilities (Jiang et al., 2015; Zhang et al., 2016;
40 Xue et al., 2021). Considering the uncertainties in physical and chemical processes (Peng et
41 al., 2021; Chen et al., 2022) and emission inventories (Elguindi et al., 2020; Jiang et al., 2022),
42 remotely sensed O₃ observations are further applied to improve the modeled O₃ concentrations
43 via data assimilation techniques (Huijnen et al., 2020; Colombi et al., 2021). In addition to
44 satellite observations, surface stations provide valuable information for air quality by
45 producing high-accuracy in situ measurements. For example, Ma et al. (2019) found that the
46 assimilation of surface observations can effectively improve the predicted surface O₃
47 concentrations; Peng et al. (2018) obtained good forecasts in short-term surface O₃ variabilities
48 by assimilating surface observations.

49 The description of O₃ photochemistry in CTMs can provide useful constraints on O₃
50 concentrations in assimilations (van Peet et al., 2018; Miyazaki et al., 2020). However, the high
51 computational cost is a potential bottleneck for rapid assimilations with high spatial resolution
52 and wide spatial coverage, which poses a possible barrier to better understanding the long-term
53 changes in tropospheric O₃ on continental or global scales. Alternatively, people may consider
54 simulations of atmospheric O₃ with the archived O₃ product and loss rates. For example, the
55 tagged-O_x mode of the GEOS-Chem model has been used to analyze the sources and transport
56 of tropospheric O₃ (Zhang et al., 2008; Zhu et al., 2017; Han et al., 2018). However, it may not

57 be an ideal choice to perform O₃ assimilations based on the tagged-O_x mode because O_x is the
58 combination of multiple species, including O₃, and thus cannot be accurately compared with
59 O₃ observations.

60 In this study, we developed the single tracer tagged-O₃ mode of the GEOS-Chem model,
61 driven by archived O₃ product and loss rates provided by GEOS-Chem full chemistry
62 simulations, to build the capability of the GEOS-Chem model for rapid simulations of
63 tropospheric O₃ (rather than O_x). The tagged-O₃ simulation was then combined with the Ozone
64 Monitoring Instrument (OMI) and China Ministry of Ecology and Environment (MEE)
65 monitoring network O₃ observations (in this paper) and United States (US) Air Quality System
66 (AQS) and European AirBase network O₃ observations (in the companion paper: Part 2, Zhu
67 et al. (2023)) via a sequential Kalman Filter (KF) assimilation system (Tang et al., 2022; Han
68 et al., 2022) to investigate the performance of single tracer simulation on O₃ assimilations.
69 Furthermore, the rapid assimilation capability based on the tagged-O₃ mode allows us to
70 perform a convenient, comparative analysis to investigate the changes in tropospheric O₃ in E.
71 China in 2015-2020 (in this paper) and the US and Europe in 2005-2020 (in the companion
72 paper: Part 2, Zhu et al. (2023)). Considering their different vertical sensitivities, a comparative
73 analysis by assimilating satellite and surface O₃ measurements is useful for better
74 characterization of O₃ changes in the surface and free troposphere and is helpful for better
75 applications of satellite and surface O₃ measurements in the future.

76 This paper is organized as follows: in Section 2, we describe the surface (MEE, AQS and
77 AirBase) and OMI O₃ observations, GEOS-Chem model and data assimilation system used in
78 this work. Tropospheric O₃ changes in E. China in 2015-2020 are then demonstrated in Section
79 3 by assimilating MEE and OMI O₃ observations. As shown in Fig. 1, five regions (i.e., North
80 China Plain (#1), Yangtze River Delta (#2), Central China (#3), Sichuan Basin (#4) and
81 Southern China (#5)) are defined within the E. China domain based on anthropogenic NO_x

82 emissions in 2015. Regions #1 and #2 are defined as highly polluted regions by excluding grids
83 with low and medium anthropogenic NO_x emissions. Tropospheric O₃ changes over these
84 regions are discussed to investigate the possible regional discrepancies in surface and free
85 tropospheric O₃ associated with different local pollution levels. Our conclusions follow in
86 Section 4.

87

88 **2. Data and Methods**

89 **2.1 Surface O₃ measurements**

90 We use MEE surface in situ O₃ concentration data (<https://quotsoft.net/air/>) for the period
91 2015-2020. These real-time monitoring stations have the ability to report hourly concentrations
92 of criteria pollutants from over 1650 sites in 2020. Concentrations were reported by the MEE
93 in ug m⁻³ under standard temperature (273 K) until 31 August 2018. This reference state was
94 changed on 1 September 2018 to 298 K. We converted the O₃ concentrations to ppb and
95 rescaled the post-August 2018 concentrations to the standard temperature (273 K) to maintain
96 consistency in the trend analysis. In addition, in situ hourly surface O₃ measurements from the
97 US AQS and European Environment Agency AirBase networks are used in the companion
98 paper (Part 2, Zhu et al. (2023)). The AQS and AirBase networks collect ambient air pollution
99 data from monitoring stations located in urban, suburban, and rural areas. We only considered
100 stations with at least 14 years of observation records in 2005-2020.

101 **2.2 OMI PROFOZ product**

102 The OMI instrument was launched in July 2004 on the Aura spacecraft with a spatial
103 resolution of 13 × 24 km (nadir view). It provides global covered measurements with
104 backscattered sunlight in the ultraviolet–visible range from 270 to 500 nm (UV1: 270–310 nm;
105 UV2: 310–365 nm; visible: 350–500 nm). In this study, we use the OMI O₃ profile retrieval
106 product (PROFOZ v0.9.3, level 2, Liu et al., 2010; Huang et al., 2017) from the Smithsonian

107 Astrophysical Observatory (SAO). The retrieval uses the vector linearized discrete ordinate
108 radiative transfer model (VLIDORT) (Spurr, 2006) and Bayesian optimal estimation. Profiles
109 of partial O₃ columns (unit: DU) are retrieved in the spectral region 270–330 nm with 24
110 vertical layers: approximately 2.5 km for each layer from the surface to approximately 60 km.

111 The following filters are applied in our analysis following Huang et al. (2017): 1) nearly
112 clear-sky scenes with effective cloud fraction < 0.3; 2) solar zenith angles (SZA) < 75°; and 3)
113 fitting root mean square (RMS, ratio of fitting residuals to assumed measurement error) < 2.0.
114 Starting in 2009, anomalies were found in OMI data and diagnosed as attenuated measured
115 radiances in certain cross-track positions. This instrument degradation has been referred to as
116 the “row anomaly”. To enhance the quality and stability of data, only across-track positions
117 between 4-11 (within 30 positions in the UV1 channels) are used in our analysis. This treatment
118 is similar to the production of row-isolated data by using across-track positions between 3-18
119 (within 60 positions in the UV2 channels) in the OMI/MLS O₃ data (Ziemke et al., 2019; Wang
120 et al., 2022).

121 The modeled tropospheric O₃ profiles in the assimilation processes and subsequent
122 analyses are convolved by using the OMI retrieval averaging kernels and a priori O₃ profile
123 based on the following equation:

$$124 \quad \hat{\mathbf{x}} = \mathbf{x}_a + \mathbf{A}(\mathbf{x} - \mathbf{x}_a) \quad (\text{Eq.1})$$

125 where $\hat{\mathbf{x}}$ is the modeled O₃ profile convolved by the retrieval averaging kernels, \mathbf{x}_a is the
126 OMI a priori O₃ profile, \mathbf{x} is the modeled O₃ profile, and \mathbf{A} is the OMI averaging kernel
127 matrix. Here $A(i, j) = \frac{\partial \hat{x}_j}{\partial x_i}$, representing the sensitivity of the retrieved partial O₃ column (DU)
128 at layer j to the change in O₃ (DU) at layer i. The unit for averaging kernels in this OMI product
129 is DU/DU and does not cancel out because the conversion from DU to ppb varies with altitude.

130 2.3 GEOS-Chem model configuration

131 The GEOS-Chem chemical transport model (<http://www.geos-chem.org>, version 12-8-1)
132 is driven by assimilated meteorological data of MERRA-2. The GEOS-Chem full-chemistry
133 simulation includes fully coupled O₃-NO_x-VOC-halogen-aerosol chemistry. Our analysis is
134 conducted at a horizontal resolution of nested 0.5°×0.625° over China, the US and Europe with
135 chemical boundary conditions archived every 3 hours from global simulations with 4°×5°
136 resolution. Emissions are computed by the Harvard-NASA Emission Component (HEMCO).
137 Global default anthropogenic emissions are from the CEDS (Community Emissions Data
138 System) (Hoesly et al., 2018). Regional emissions are replaced by MEIC (Multiresolution
139 Emission Inventory for China) in China, MIX in other regions of Asia (Li et al., 2017) and
140 NEI2011 in the US. Open fire emissions are from the Global Fire Emissions Database (GFED4)
141 (van der Werf et al., 2010).

142 Following Jiang et al. (2022), the total anthropogenic NO_x and VOC emissions in the
143 GEOS-Chem model are scaled with the corresponding bottom-up inventories (MEIC for China,
144 NEI2014 for the US, and ECLIPSE for Europe) so that the modeled surface nitrogen dioxide
145 (NO₂) and O₃ concentrations in the a priori simulations are identical to Jiang et al. (2022) in
146 2005-2018. The total anthropogenic NO_x and VOC emissions in 2019-2020 in China, the US
147 and Europe are further scaled based on linear projections. The total anthropogenic NO_x
148 emissions in the a priori simulations declined by 53% (US) and 50% (Europe) in 2005-2020
149 and by 19% (China) in 2015-2020. The total anthropogenic VOC emissions in the a priori
150 simulations declined by 19% (US) and 33% (Europe) in 2005-2020 and increased by 1%
151 (China) in 2015-2020. We refer the reader to Jiang et al. (2022) for the details of the model
152 configuration and performance, particularly the modeled trends of surface and tropospheric
153 column NO₂ in 2005-2018.

154 **2.4 Data assimilation approach**

155 We employ the sequential KF to assimilate O₃ observations, which has been used in
156 recent studies to optimize tropospheric CO concentrations (Tang et al., 2022; Han et al., 2022).
157 As a brief description of the assimilation algorithm, the forward model (**M**) predicts the O₃
158 concentration (\mathbf{x}_{at}) at time t:

$$159 \quad \mathbf{x}_{at} = \mathbf{M}_t \mathbf{x}_{t-1} \quad (\text{Eq. 2})$$

160 The optimized O₃ concentrations can be expressed as:

$$161 \quad \mathbf{x}_t = \mathbf{x}_{at} + \mathbf{G}_t (\mathbf{y}_t - \mathbf{K}_t \mathbf{x}_{at}) \quad (\text{Eq. 3})$$

162 where \mathbf{y}_t is the observation and \mathbf{K}_t represents the operation operator that projects O₃
163 concentrations from the model space to the observation space. \mathbf{G}_t is the KF gain matrix, which
164 can be described as:

$$165 \quad \mathbf{G}_t = \mathbf{S}_{at} \mathbf{K}_t^T (\mathbf{K}_t \mathbf{S}_{at} \mathbf{K}_t^T + \mathbf{S}_\epsilon)^{-1} \quad (\text{Eq. 4})$$

166 where \mathbf{S}_{at} and \mathbf{S}_ϵ are the model and observation covariances, respectively. The optimized O₃
167 concentrations provided by Eq. 3 are then forwarded (hourly) to Eq. 2. The model errors are
168 assumed to be 50%. The measurement errors are calculated as $\epsilon_0 = ermax + 0.0075 * \Pi_0$,
169 where *ermax* is the base error (1.5 µg m⁻³) and Π_0 represents the observed O₃ concentrations
170 (unit: µg m⁻³). The representation errors are calculated as $\epsilon_r = \gamma \epsilon_0 \sqrt{\Delta l / L}$, where γ is a scaling
171 factor (0.5), Δl is the model resolution (~56 km in this study), and L represents the range that
172 the observation can reflect, which depends on the station type (2 km for urban, 4 km for
173 suburban). The total observation error is then defined as $\epsilon_t = \sqrt{\epsilon_0^2 + \epsilon_r^2}$. Following Tang et
174 al. (2022), grid-based superobservations (0.5°×0.625°) were created to reduce the influence of
175 representative errors.

176

177 **3. Results and Discussion**

178 **3.1 GEOS-Chem tagged-O₃ simulation**

179 A new chemical mechanism was developed in this work to allow the running of the single

180 tracer tagged-O₃ mode. As shown in Fig. S1 (see the SI), the package of the Kinetic
181 PreProcessor (KPP) module was modified to define the production (PO₃) and loss (LO₃) of
182 O₃. The GEOS-Chem full-chemistry simulations with the updated KPP module were then
183 performed to produce PO₃ and LO₃ every 20 minutes. Here the 20 minutes is selected to be
184 the same as the chemical time step in GEOS-Chem full-chemistry mode to ensure consistency
185 between tagged-O₃ and full chemistry simulations. Finally, the single tracer tagged-O₃ mode
186 (tagged_o3_mod.F90) was performed by reading the archived PO₃ and LO₃ provided by the
187 full-chemistry simulations. Because we are interested in tropospheric chemistry, we archived
188 O₃ concentrations instead of O₃ production and loss rates in the stratosphere in the full
189 chemistry simulations. The archived stratospheric O₃ concentrations were read in the tagged-
190 O₃ simulation process as boundary conditions to ensure a reasonable stratospheric-tropospheric
191 O₃ exchange.

192 Why is tagged-O₃ simulation useful if we must run the full-chemistry simulation first to
193 produce PO₃ and LO₃? Table 1 shows the computation costs (hours of wall time per simulation
194 year) by different GEOS-Chem simulation types in this work. We find 91%-94% reductions in
195 the computation costs with respect to full-chemistry simulations: 57.5 and 5.2 hours at the
196 global scale (4°×5°), 80.2 and 4.5 hours within the nested China domain (0.5°×0.625°), 160.7
197 and 9.4 hours within the nested US domain (0.5°×0.625°) and 103.4 and 6 hours within the
198 nested Europe domain (0.5°×0.625°) by full chemistry and tagged-O₃ modes, respectively.
199 Consequently, once the PO₃ and LO₃ are produced, the additional computational costs of
200 performing tagged-O₃ simulation are almost negligible. The low computational costs of the
201 tagged-O₃ simulation allow us to design and perform different assimilation experiments much
202 more efficiently.

203 Here we evaluate the consistency in modeled O₃ concentrations between tagged-O₃ and
204 full-chemistry simulations. Fig. 2A-E show the annual and seasonal averages of surface

205 maximum daily 8-hour average (MDA8) O₃ over E. China in 2015-2020 from the full-
206 chemistry simulation. The modeled surface MDA8 O₃ concentrations are as high as 60-70 ppb
207 in the summer and as low as 10-20 ppb in the winter over northern China. The simulation with
208 the tagged-O₃ mode (Fig. 2F-J) demonstrates spatial consistency with the full-chemistry
209 simulation (Fig. 2A-E) and temporal consistency at both the daily (Fig. 3A) and monthly (Fig.
210 3B) scales in 2015-2020. In contrast, there are large discrepancies between full-chemistry (Fig.
211 2A-E) and tagged-O_x (Fig. 2K-O) simulations. As shown in Fig. 3, the O_x concentrations are
212 higher than the O₃ concentrations by approximately 6 ppb, and the relative difference can reach
213 40% in the winter. Similarly, Fig. S2 (see the SI) shows the annual and seasonal averages of
214 surface MDA8 O₃ over the US and Europe in 2005-2020 from the full-chemistry and tagged-
215 O₃ simulations. Similar to China, we find good spatial (Fig. S2) and temporal (Fig. S3, see the
216 SI) consistencies in surface MDA8 O₃ between tagged-O₃ and full-chemistry simulations over
217 the US and Europe in 2005-2020. Our analysis thus indicates the reliability of the tagged-O₃
218 simulations developed in this work.

219 3.2 Surface O₃ by assimilating MEE O₃ observations

220 We first investigate the effects of surface O₃ observations on the tagged-O₃-based
221 assimilations. O₃ at the surface level is formed by precursors mixed in the planetary boundary
222 layer (PBL). Thus, it may not be accurate to assume that the differences between simulated and
223 observed surface O₃ concentrations are completely caused by biased O₃ production and loss at
224 the surface level. Here we adjust O₃ concentrations at all levels within the PBL when
225 assimilating surface O₃ observations:

$$226 \quad \Delta O_3^l = \Delta O_3^1 \times 0.8^{l-1} \quad (\text{Eq. 5})$$

227 where ΔO_3^1 is the adjustment at the surface level calculated with Eq. 3; ΔO_3^l is the adjustment
228 at model level l , which is based on ΔO_3^1 but decays exponentially with the increase in model
229 level. We note that Eq. 5 is defined empirically, as we find that the assimilated O₃ matches

230 better with surface O₃ observations. More efforts are needed in the future to evaluate the
231 reliability of this empirical method.

232 Fig. 4A-E show the annual and seasonal averages of surface MDA8 O₃ observations from
233 MEE stations in 2015-2020. Fig. 4K-O further show the annual and seasonal averages of the a
234 posteriori O₃ concentrations by assimilating the MEE O₃ observations. As shown in Fig. 5, the
235 assimilated O₃ concentrations (blue lines) show good agreements with MEE O₃ observations
236 (red lines): the mean surface MDA8 O₃ in 2015-2020 are 42.9, 41.8 and 42.1 ppb (E. China),
237 42.3, 45.6 and 47.6 ppb (North China Plain), 44.5, 45.0 and 44.9 ppb (Yangtze River Delta),
238 44.7, 43.1 and 43.5 ppb (Central China), 45.3, 37.5 and 36.9 ppb (Sichuan Basin), and 43.0,
239 39.2 and 38.3 ppb (Southern China) in the a priori simulations, a posteriori simulations and
240 MEE observations, respectively. As we expected, MDA8 O₃ concentrations are higher over
241 areas with higher anthropogenic NO_x emissions, for example, 45.6 and 45.0 ppb in the North
242 China Plain and Yangtze River Delta, respectively, in contrast to 43.1, 37.5 and 39.2 ppb in
243 Central China, Sichuan Basin and Southern China, respectively.

244 As shown in Fig. 5A, there are good agreements between the a priori and a posteriori O₃
245 concentrations over E. China except a larger difference in the summer. However, as shown in
246 Fig. 4P-T, the good agreements between the a priori and a posteriori O₃ concentrations are
247 caused by the counterbalance of positive biases (i.e., overestimated surface O₃ in the a priori
248 simulations over southern China) and negative biases (i.e., underestimated surface O₃ in the a
249 priori simulations over northern China). The good agreements in Fig. 5A thus cannot represent
250 good performance in the simulations of surface O₃ concentrations. Furthermore, surface O₃
251 concentrations are maximum in June in the North China Plain, May and August in the Yangtze
252 River Delta, Central China and Sichuan Basin, September-October in Southern China (Fig. 5).
253 The assimilations exhibit noticeable declines in surface O₃ concentrations over regions #2-5 in
254 June-July, and the declines are underestimated by the a priori simulations. The inaccurate

255 simulations of surface O₃ concentrations in June-July thus result in overestimated surface O₃
256 concentrations in the summer.

257 **3.3 Rapid increasing trends in surface O₃ concentrations**

258 Here we further investigate the changes in surface O₃ concentrations from observations
259 and assimilations. As shown in Fig. 6F-J, the a priori simulation suggests slightly increasing
260 trends of MDA8 O₃ in 2015-2020: 0.27 (spring), -0.23 (summer), 0.41 (autumn) and 0.40
261 (winter) ppb yr⁻¹, and the relative increasing trends are 0.6 (spring), -0.4 (summer), 1.0
262 (autumn) and 1.4 (winter) % yr⁻¹. The a priori simulation suggests increasing trends of surface
263 O₃ concentrations in the summer over areas with higher local pollution levels, for example,
264 0.61 and 0.58 ppb yr⁻¹ over the North China Plain and Yangtze River Delta, respectively, and
265 decreasing trends of surface O₃ concentrations in the summer over areas with lower local
266 pollution levels, for example, -0.10, -1.01 and -1.06 ppb yr⁻¹ over Central China, Sichuan Basin
267 and Southern China, respectively. The decreasing trends over areas with lower local pollution
268 levels in the simulations are not surprising, given the decreases in anthropogenic NO_x
269 emissions (Zheng et al., 2018; Jiang et al., 2022) and the reported NO_x-limited O₃ nonlinear
270 chemical regimes in model simulations (Chen et al., 2021; Liu et al., 2021).

271 In contrast, the increasing trends in surface O₃ are much stronger in the assimilations. As
272 shown in Table 2.1, our assimilation suggests 1.60 (spring), 1.16 (summer), 1.47 (autumn) and
273 0.80 (winter) ppb yr⁻¹ increases in surface O₃ over E. China in 2015-2020, and the relative
274 increasing trends are 3.4 (spring), 2.2 (summer), 3.7 (autumn) and 2.7 (winter) % yr⁻¹. The
275 increasing trends are weaker when the modeled surface O₃ concentrations are averaged over E.
276 China (Table 2.2) instead of sampling at the locations and times of MEE observations: 0.71
277 (spring), 0.36 (summer), 0.69 (autumn) and 0.54 (winter) ppb yr⁻¹ because most MEE stations
278 are urban sites. Our analysis thus indicates a noticeable underestimation in the increasing trends
279 of surface O₃ concentrations in China in the a priori simulations, particularly in the summer,

280 despite the anthropogenic NO_x and VOC emissions having been scaled in the simulations
281 following Jiang et al. (2022).

282 The changes in surface O_3 concentrations have significant regional and seasonal
283 discrepancies. As shown in Tables S1-S5 (see the SI), our assimilations demonstrate strong
284 increasing trends in surface O_3 concentrations in 2015-2020 in the spring (1.94 ppb yr^{-1} or 3.8%
285 yr^{-1}) and summer (2.52 ppb yr^{-1} or $4.0\% \text{ yr}^{-1}$) over the North China Plain; in the spring (2.21
286 ppb yr^{-1} or $4.4\% \text{ yr}^{-1}$) and autumn (1.84 ppb yr^{-1} or $4.1\% \text{ yr}^{-1}$) over the Yangtze River Delta; in
287 the spring (2.07 ppb yr^{-1} or $4.3\% \text{ yr}^{-1}$) and autumn (2.09 ppb yr^{-1} or $4.7\% \text{ yr}^{-1}$) over Central
288 China; in the spring (1.69 ppb yr^{-1} or $3.8\% \text{ yr}^{-1}$) over the Sichuan Basin; and in the autumn
289 (2.21 ppb yr^{-1} or $4.9\% \text{ yr}^{-1}$) over Southern China. While surface O_3 concentrations are higher
290 over areas with higher anthropogenic NO_x emissions, the increasing trends in surface O_3
291 concentrations over Central China and Southern China are comparable with those in the North
292 China Plain and Yangtze River Delta. Our analysis advises more attention to O_3 pollution in
293 spring and autumn over areas with lower anthropogenic NO_x emissions because of the rapid
294 increases in surface O_3 concentrations.

295 **3.4 Tropospheric O_3 columns by assimilating OMI O_3 observations**

296 Fig. 7A-E show the annual and seasonal averages of tropospheric OMI O_3 columns in
297 2015-2020. OMI is sensitive to O_3 at different vertical levels (Huang et al., 2017; Fu et al.,
298 2018), and thus, the standard KF algorithm (Eq. 3) was employed to adjust tropospheric O_3
299 vertical profiles with the application of OMI O_3 averaging kernels. Fig. 7K-O show the annual
300 and seasonal averages of the a posteriori tropospheric O_3 columns by assimilating OMI O_3
301 observations. The assimilated tropospheric O_3 columns show good agreement with OMI O_3
302 observations: the mean tropospheric O_3 columns in 2015-2020 (Table 2.3) are 37.1 DU in the
303 a priori simulations, and 37.9 and 38.0 DU in the a posteriori simulation and OMI observations,
304 respectively. Furthermore, as shown in Fig. 8, the trends of tropospheric O_3 columns in 2015-

305 2020 (Table 2.3) are 0.02 DU yr^{-1} in the a priori simulations, and -0.17 and -0.30 DU yr^{-1} in
306 the a posteriori simulation and OMI observations, respectively.

307 The discrepancies between the a priori and a posteriori tropospheric O_3 columns by
308 assimilating OMI O_3 observations (Fig. 7) are smaller than those in surface O_3 concentrations
309 (Fig. 4). A better simulation capability in tropospheric column O_3 is expected because model
310 simulation with $0.5^\circ \times 0.625^\circ$ horizontal resolution may not be enough to accurately resolve O_3
311 nonlinear chemical regimes over urban surface stations. Furthermore, in contrast to the wide
312 distributions of increasing trends of O_3 at the surface level (Fig. 6), both OMI O_3 observations
313 (-0.30 DU yr^{-1}) and the OMI-based assimilations (-0.17 DU yr^{-1}) suggest decreasing trends in
314 tropospheric O_3 columns over E. Asia in 2015-2020 (Fig. 8). The decreasing trends are stronger
315 in the summer and weaker in the spring. However, the trends shown in Fig. 8 may not represent
316 the actual tropospheric O_3 changes well because the convolution of OMI O_3 averaging kernels
317 on the output O_3 profiles can affect the weights of the derived tropospheric columns to O_3 at
318 different vertical levels.

319 Consequently, Fig. 9 further shows the annual and seasonal averages of tropospheric O_3
320 columns from a priori and a posteriori simulations, in which the output O_3 profiles are not
321 convolved with OMI retrieval averaging kernels so that they can better represent the actual
322 atmospheric O_3 state. As shown in Fig. 10, the assimilated tropospheric O_3 columns are 37.2
323 and 38.8 DU (E. China), 41.4 and 43.7 DU (North China Plain), 46.0 and 48.1 DU (Yangtze
324 River Delta), 45.9 and 48.1 DU (Central China), 42.6 and 44.6 DU (Sichuan Basin), 38.8 and
325 40.6 DU (Southern China) in 2015-2020 by assimilating MEE and OMI O_3 observations,
326 respectively. In contrast to the higher surface MDA8 O_3 concentrations over areas with higher
327 anthropogenic NO_x emissions, tropospheric O_3 columns over Central China and the Sichuan
328 Basin are even higher than those over the highly polluted North China Plain. In addition,
329 tropospheric O_3 columns by assimilating MEE surface O_3 observations are lower than those by

330 assimilating OMI O₃ observations, and their difference is larger in the summer and smaller in
331 the winter.

332 The assimilated tropospheric O₃ columns are maximum in June-July in North China Plain
333 (Fig. 10). However, the assimilated tropospheric O₃ columns are maximum in March-May over
334 other regions that are dramatically different with surface O₃ (Fig. 5). The similar seasonality
335 between surface and free tropospheric O₃ over highly polluted North China Plain reflects the
336 impact of local emissions. The different seasonality over other regions may represent the
337 contributions from free tropospheric O₃ transport. While the Yangtze River Delta is defined as
338 a highly polluted region, its area is much smaller than North China Plain (Fig. 1) and thus the
339 impact of local emissions on tropospheric O₃ columns over the Yangtze River Delta may not
340 be as strong as the North China Plain. Furthermore, as shown in Fig. 11, the impacts of different
341 surface and satellite O₃ observations on the assimilated O₃ vertical profiles are limited. The
342 assimilation of MEE surface O₃ observations leads to decreases in O₃ concentrations in the
343 lower troposphere from the surface to 600 hPa levels over the Sichuan Basin and Southern
344 China; the assimilation of OMI O₃ observations leads to enhancement in O₃ concentrations in
345 the middle and upper troposphere over the highly polluted North China Plain.

346 As shown in Fig. 12, the trends of tropospheric O₃ columns in 2015-2020 are 0.06, 0.25
347 and -0.10 DU yr⁻¹ (E. China), 0.26, 0.66 and 0.12 DU yr⁻¹ (North China Plain), 0.28, 0.60 and
348 0.13 DU yr⁻¹ (Yangtze River Delta), 0.09, 0.46 and -0.06 DU yr⁻¹ (Central China), -0.14, 0.17
349 and -0.29 DU yr⁻¹ (Sichuan Basin), -0.08, 0.15 and -0.25 DU yr⁻¹ (Southern China) in the a
350 priori simulations and a posteriori simulations by assimilating MEE and OMI O₃ observations,
351 respectively. The higher positive trends by assimilating MEE observations are expected, given
352 the increasing trends in surface O₃ concentrations (1.77 ppb yr⁻¹) and decreasing trends in OMI
353 O₃ concentrations (-0.30 DU yr⁻¹) over E. China. The stronger increasing trends in free
354 tropospheric O₃ over the highly polluted North China Plain and Yangtze River Delta may

355 reflect the larger contributions of local emissions to tropospheric O₃ columns over highly
356 polluted areas, and the increasing trends are stronger in autumn and winter. The large
357 discrepancy between assimilations by assimilating surface and satellite observations further
358 indicates the possible uncertainties in the derived free tropospheric O₃ changes. Assimilations
359 of both surface and satellite observations, as shown in this work, are thus expected to provide
360 more information to better describe the changes in free tropospheric O₃.

361 **4. Conclusion**

362 The single tracer tagged-O₃ mode was developed in this work to build the capability of
363 the GEOS-Chem model for rapid simulations of tropospheric O₃. The tagged-O₃ mode
364 demonstrates high consistency with GEOS-Chem full-chemistry simulation. In contrast, the O_x
365 concentrations provided by the tagged-O_x mode are higher than the O₃ concentrations by
366 approximately 6 ppb, and the relative difference can reach 40% in the winter. The
367 computational costs of the tagged-O₃ mode are reduced by approximately 91-94% with respect
368 to the full-chemistry mode. For example, the computational costs (hours of wall time per
369 simulation year) are 57.5 and 5.2 hours at the global scale (4°×5°), 80.2 and 4.5 hours within
370 the nested China domain (0.5°×0.625°), 160.7 and 9.4 hours within the nested US domain
371 (0.5°×0.625°) and 103.4 and 6 hours within the nested Europe domain (0.5°×0.625°) by full
372 chemistry and tagged-O₃ simulations, respectively. The low computational costs of the tagged-
373 O₃ simulation thus allow us to design and perform different assimilation experiments much
374 more efficiently.

375 The tagged-O₃ simulation was combined with MEE and OMI O₃ observations to
376 investigate the changes in tropospheric O₃ over E. Asia in 2015-2020. The assimilated O₃
377 concentrations demonstrate good agreement with O₃ observations: surface O₃ concentrations
378 are 42.9, 41.8 and 42.1 ppb over E. China in a priori and a posteriori simulations and MEE O₃
379 observations, respectively; tropospheric O₃ columns are 37.1, 37.9 and 38.0 DU over E. China

380 in a priori and a posteriori simulations (convolved with OMI retrieval averaging kernels) and
381 OMI O₃ observations, respectively. We find noticeable biases in modeled surface O₃
382 concentrations, for example, overestimated surface O₃ over southern China and underestimated
383 surface O₃ over northern China. The assimilations indicate rapidly increasing trends of surface
384 O₃ concentrations by 1.60 (spring), 1.16 (summer), 1.47 (autumn) and 0.80 (winter) ppb yr⁻¹
385 over E. China in 2015-2020, and the increasing trends are underestimated by the a priori
386 simulations. While surface O₃ concentrations are higher over areas with higher anthropogenic
387 NO_x emissions, we find that the increasing trends in surface O₃ concentrations over Central
388 China and Southern China are comparable with those in the North China Plain and Yangtze
389 River Delta. Our analysis thus advises more attention to O₃ pollution in spring and autumn over
390 areas with lower anthropogenic NO_x emissions because of the rapid increases in surface O₃
391 concentrations.

392 Furthermore, the trends in assimilated tropospheric O₃ columns in 2015-2020 are 0.25
393 and -0.10 DU yr⁻¹ (E. China), 0.66 and 0.12 DU yr⁻¹ (North China Plain), 0.60 and 0.13 DU yr⁻¹
394 (Yangtze River Delta), 0.46 and -0.06 DU yr⁻¹ (Central China), 0.17 and -0.29 DU yr⁻¹
395 (Sichuan Basin), 0.15 and -0.25 DU yr⁻¹ (Southern China) by assimilating MEE surface and
396 OMI O₃ observations, respectively. The stronger increasing trends in tropospheric O₃ columns
397 over the highly polluted North China Plain and Yangtze River Delta may reflect the larger
398 contributions of local emissions to tropospheric O₃ columns over highly polluted areas. The
399 large discrepancy between assimilations by assimilating surface and satellite observations
400 further indicates the possible uncertainties in the derived free tropospheric O₃ changes. This
401 work demonstrates the importance of data assimilation techniques to provide extension and
402 interpretation of O₃ observations.

403

404 **Code and data availability:** The MEE O₃ data can be downloaded from
405 <https://quotsoft.net/air/>. The AQS and AirBase surface O₃ data can be downloaded from
406 <https://www.eea.europa.eu/data-and-maps/data/aqereporting-8> and
407 https://aq5.epa.gov/aqsweb/airdata/download_files.html#Row. The OMI PROFOZ product
408 can be acquired at
409 <https://avdc.gsfc.nasa.gov/pub/data/satellite/Aura/OMI/V03/L2/OMPROFOZ/>. The GEOS-
410 Chem model (version 12.8.1) can be downloaded from [http://wiki.seas.harvard.edu/geos-](http://wiki.seas.harvard.edu/geos-chem/index.php/GEOS-Chem_12#12.8.1)
411 [chem/index.php/GEOS-Chem_12#12.8.1](http://wiki.seas.harvard.edu/geos-chem/index.php/GEOS-Chem_12#12.8.1). The KPP module for tagged-O₃ simulations can be
412 downloaded from <https://doi.org/10.5281/zenodo.7545944>.

413

414 **Author Contributions:** Z.J. designed the research. R.Z. developed the model code and
415 performed the research. Z.J. and R.Z. wrote the manuscript. X.L. provided instruction for the
416 usage of OMI data. All authors contributed to discussions and editing the manuscript.

417

418 **Competing interests:** The contact author has declared that neither they nor their co-authors
419 have any competing interests.

420

421 **Acknowledgments:** We thank the China Ministry of Ecology and Environment (MEE), the
422 United States Environmental Protection Agency and the European Environmental Agency for
423 providing the surface O₃ measurements. The numerical calculations in this paper have been
424 done on the supercomputing system in the Supercomputing Center of University of Science
425 and Technology of China. This work was supported by the Hundred Talents Program of
426 Chinese Academy of Science and National Natural Science Foundation of China (42277082,
427 41721002).

Table 2. Averages (with units ppb or DU) and trends (with units ppb yr⁻¹ or DU yr⁻¹) of surface and tropospheric column O₃ concentrations in 2015-2020 over E. China from observations (MEE and OMI) and a priori and a posteriori (KF) simulations. T2.1): the modeled surface O₃ is sampled at the locations and times of MEE surface O₃ observations; T2.2): the modeled surface O₃ is averaged over E. China (land only); T2.3): the output O₃ profiles from the a priori and a posteriori simulations are convolved with OMI O₃ averaging kernels; T2.4): the output O₃ profiles are NOT convolved with OMI O₃ averaging kernels.

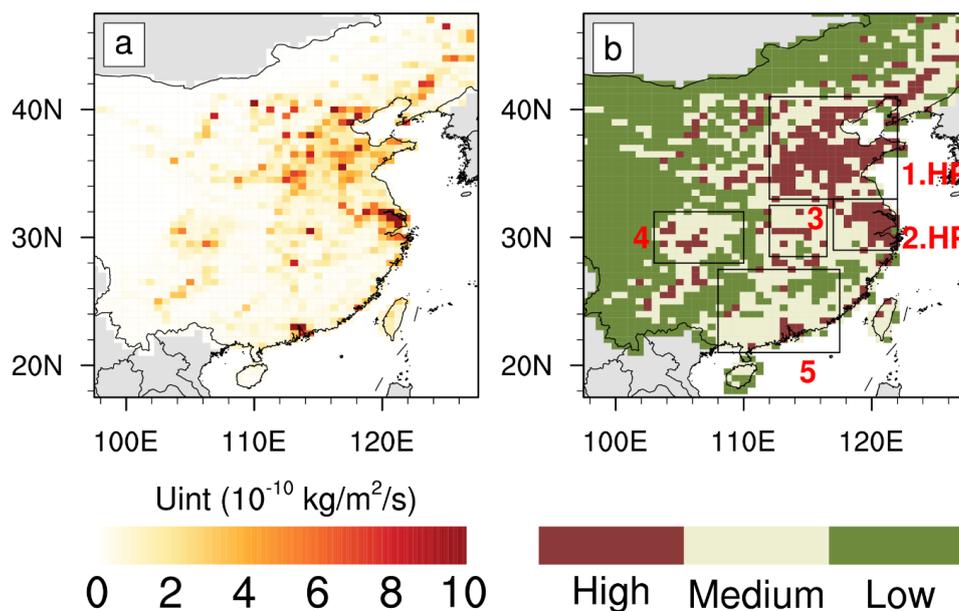

Fig. 1. Anthropogenic NO_x emissions over E. China in 2015; (b) Region definitions for the North China Plain (#1), Yangtze River Delta (#2), Central China (#3), Sichuan Basin (#4) and Southern China (#5). The different colors (red, gray and green) represent grids with high (highest 15%), medium (15-50%) and low (lowest 50%) anthropogenic NO_x emissions. Regions #1 and #2 are defined as highly polluted (HP) regions by excluding grids with low and medium anthropogenic NO_x emissions.

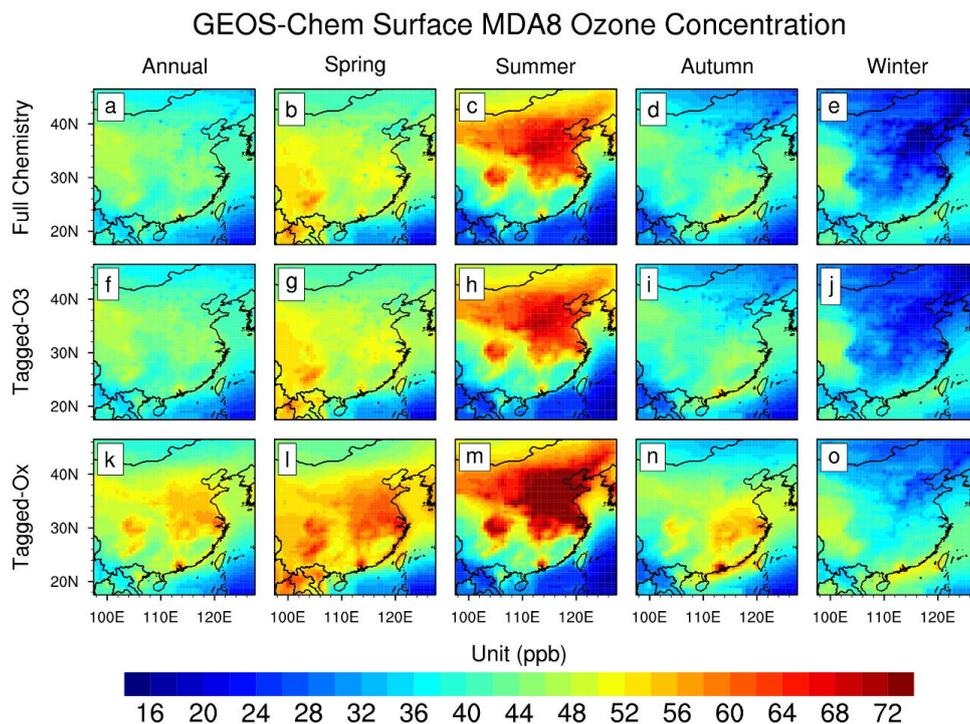

Fig. 2. Surface MDA8 O₃ in 2015-2020 (annual and seasonal averages) simulated by GEOS-Chem model with (A-E) full chemistry mode; (F-J) tagged-O₃ mode; and (K-O) tagged-O_x mode. The 8-hour range of surface O_x is selected according to the time range of MDA8 O₃.

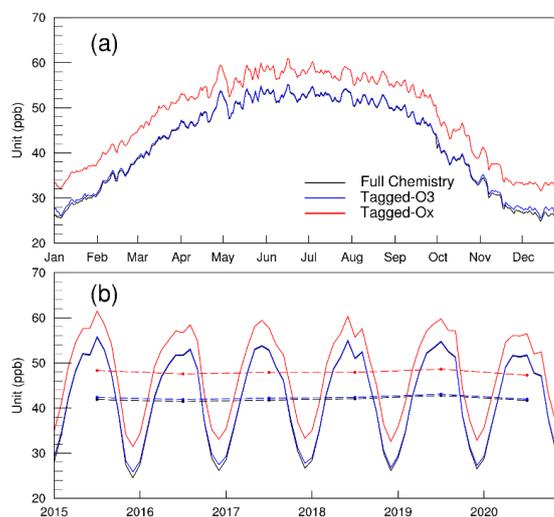

Fig. 3. (A) Daily averages of surface MDA8 O₃ over E. China in 2015-2020 from GEOS-Chem full chemistry (black), tagged-O₃ (blue) and tagged-O_x (red) simulations; (B) Monthly averages of MDA8 O₃. The dashed lines in panel B are annual averages.

GEOS-Chem & MEE Surface MDA8 Ozone Concentration

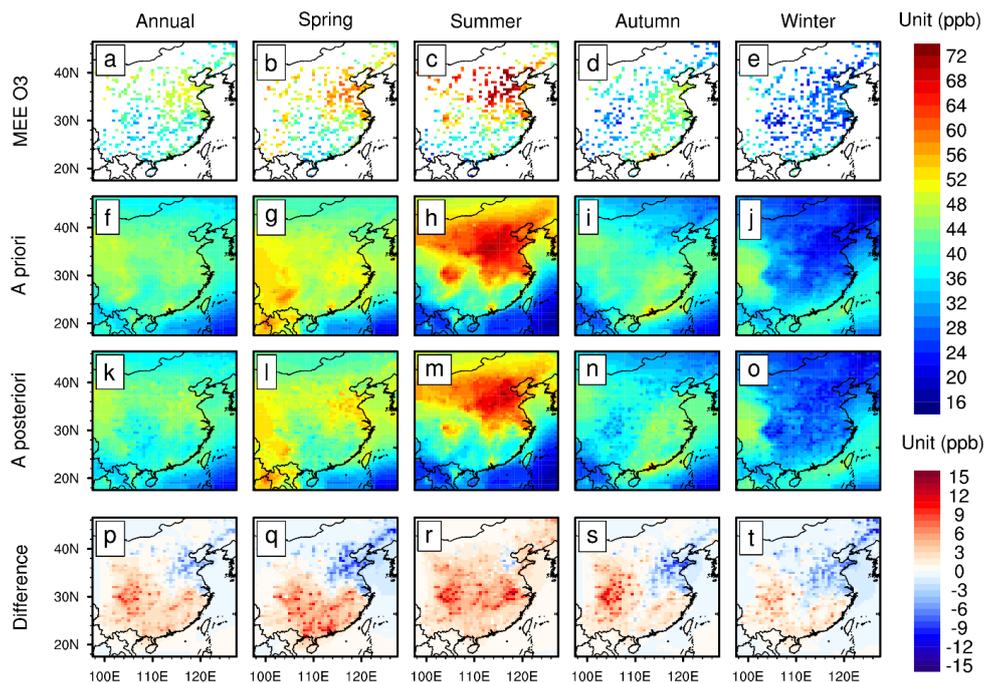

Fig. 4. Surface MDA8 O₃ in 2015-2020 (annual and seasonal averages) from (A-E) MEE stations; (F-J) GEOS-Chem a priori simulation; (K-O) GEOS-Chem a posteriori simulation by assimilating MEE O₃ observations. (P-T) bias in the a priori simulations calculated by a priori minus a posteriori O₃ concentrations.

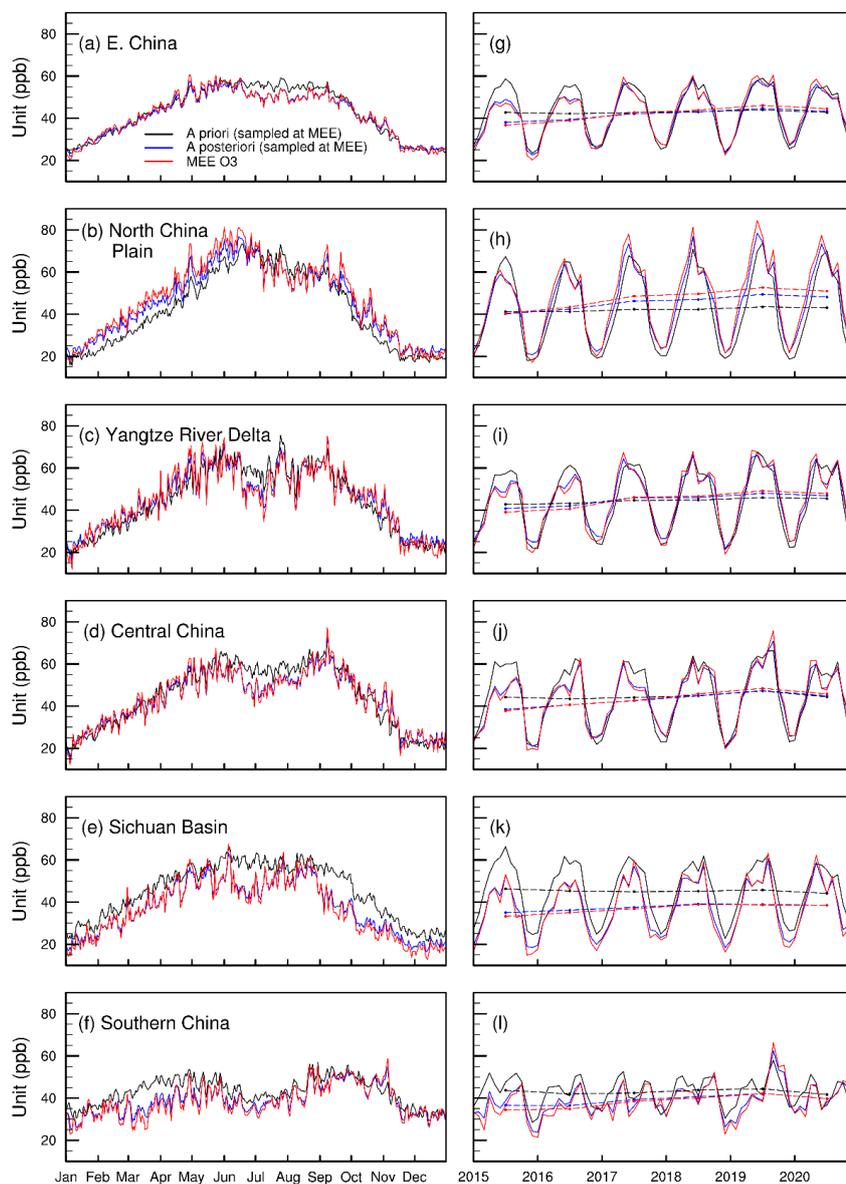

Fig. 5. (A-F) Daily averages of surface MDA8 O₃ in 2015-2020 from MEE stations (red) and GEOS-Chem a priori (black) and a posteriori (blue) simulations by assimilating MEE O₃ observations. (G-L) Monthly averages of MDA8 O₃. The dashed lines in panels G-L are annual averages.

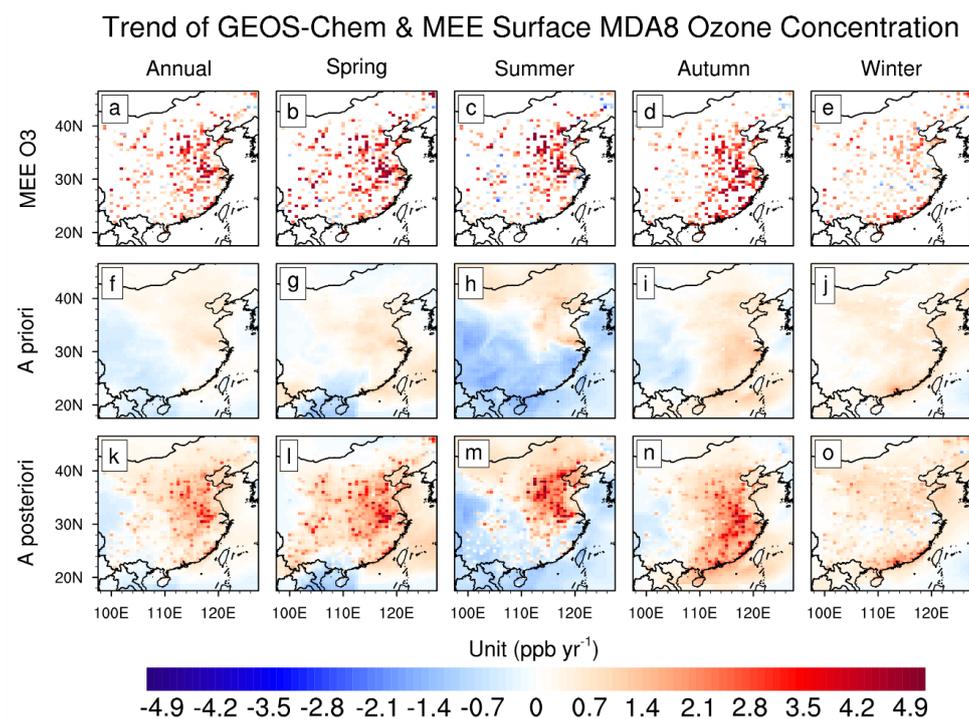

Fig. 6. Trends of surface MDA8 O₃ in 2015-2020 (annual and seasonal averages) from (A-E) MEE stations; (F-J) GEOS-Chem a priori simulation; (K-O) GEOS-Chem a posteriori simulation by assimilating MEE O₃ observations.

OMI & GEOS-Chem Tropospheric Columns Convolved with OMI AKs

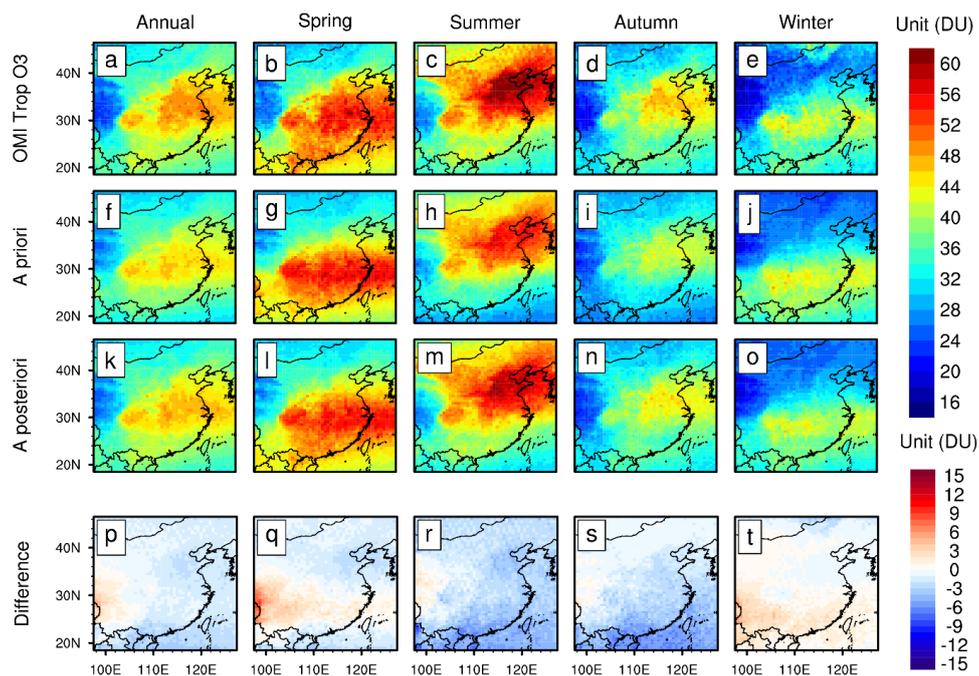

Fig. 7. Tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A-E) OMI observations; (F-J) GEOS-Chem a priori simulation; (K-O) GEOS-Chem a posteriori simulation by assimilating OMI O₃ observations. (P-T) bias in the a priori simulations calculated by a priori minus a posteriori tropospheric O₃ columns. The output O₃ profiles are convolved with OMI averaging kernels.

Trend of OMI & GEOS-Chem Tropospheric Columns Convolved with OMI AKs

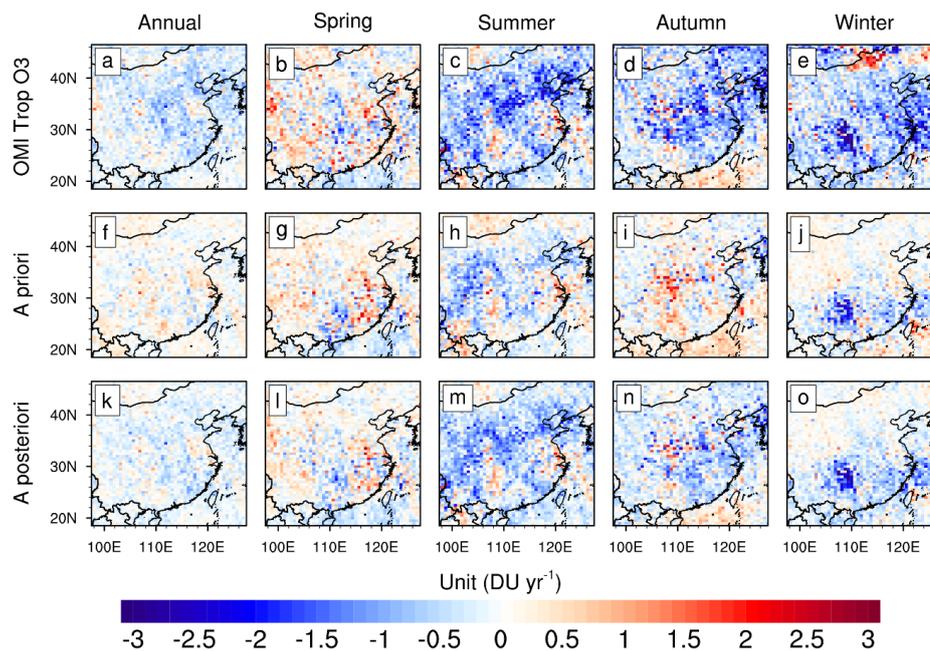

Fig. 8. Trends of tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A-E) OMI observations; (F-J) GEOS-Chem a priori simulation; (K-O) GEOS-Chem a posteriori simulation by assimilating OMI O₃ observations. The output O₃ profiles are convolved with OMI averaging kernels.

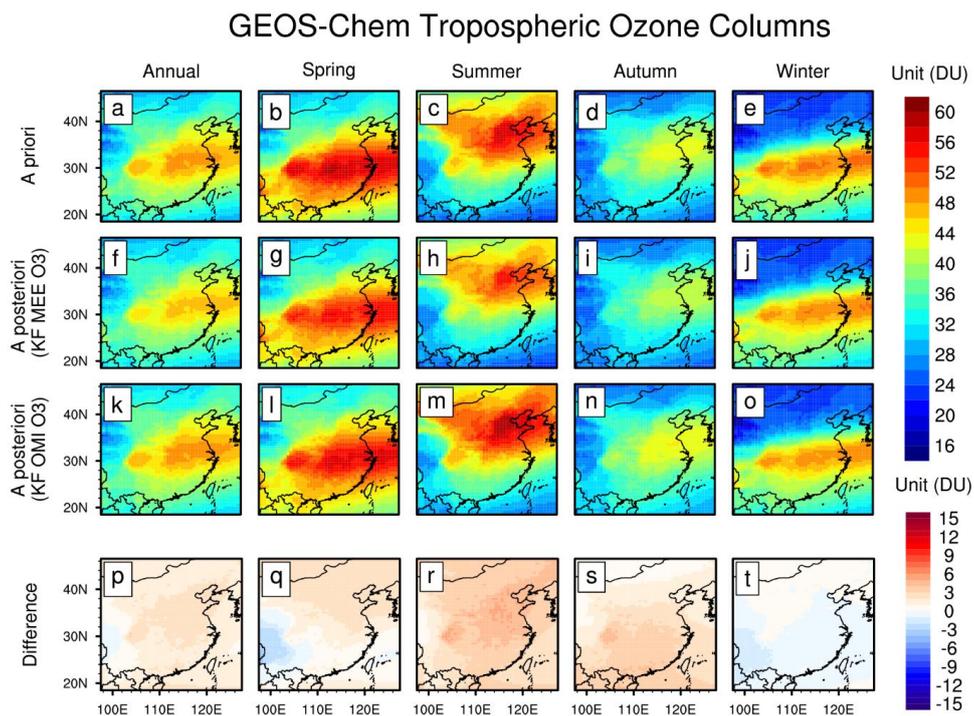

Fig. 9. Tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A-E) GEOS-Chem a priori simulation; (F-J) assimilations of MEE surface O₃ observations; (K-O) assimilations of OMI O₃ observations. (P-T) difference in tropospheric O₃ columns calculated by OMI-based assimilations minus MEE-based assimilations.

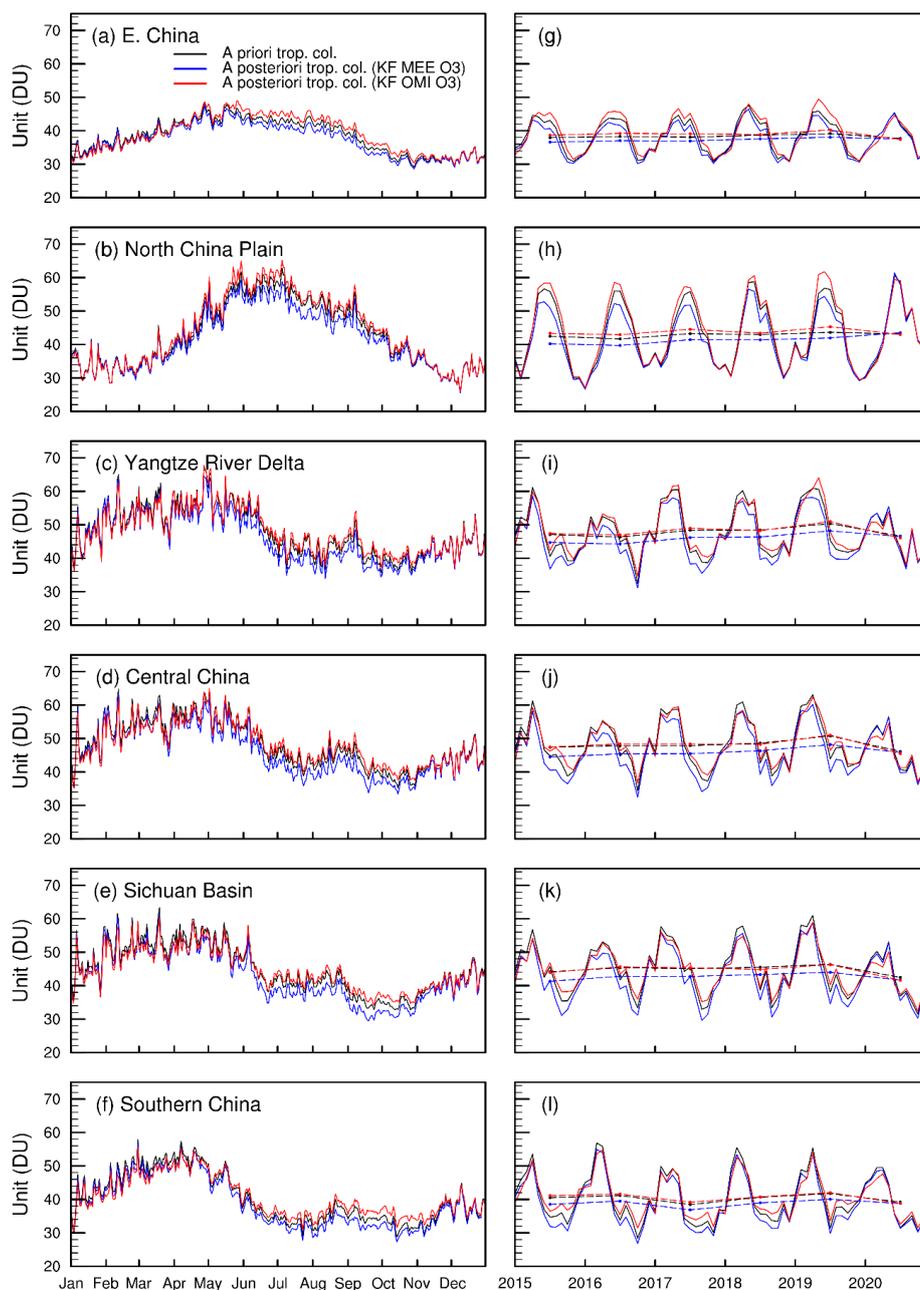

Fig. 10. (A-F) Daily averages of tropospheric O₃ columns in 2015-2020 from GEOS-Chem a priori simulation (black) and a posteriori simulations by assimilating MEE (blue) and OMI (red) O₃ observations. (G-L) Monthly averages of tropospheric O₃ columns. The dashed lines in panels G-L are annual averages.

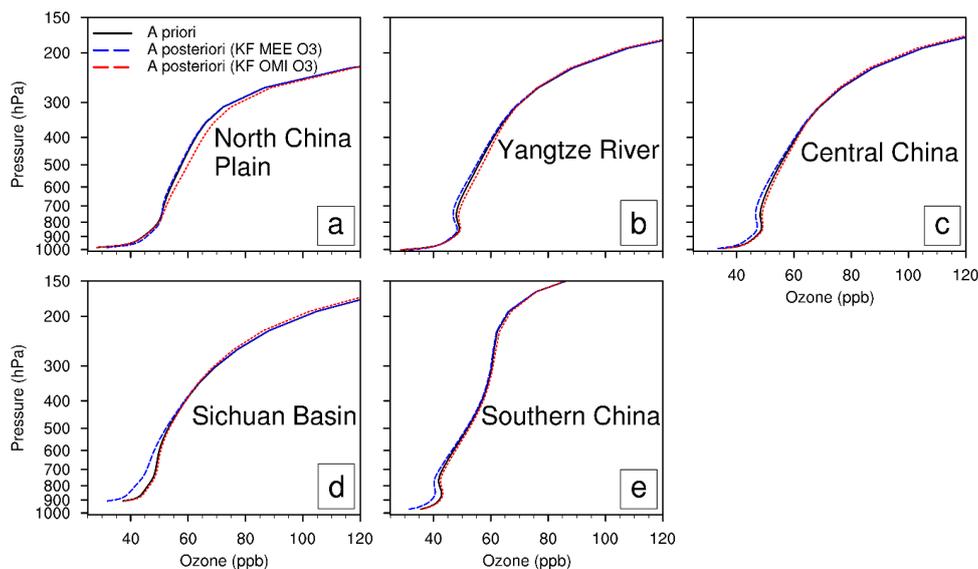

Fig. 11. Averages of O₃ vertical profiles in 2015-2020 from GEOS-Chem a priori (black) and a posteriori simulations by assimilating MEE (blue) and OMI (red) O₃ observations.

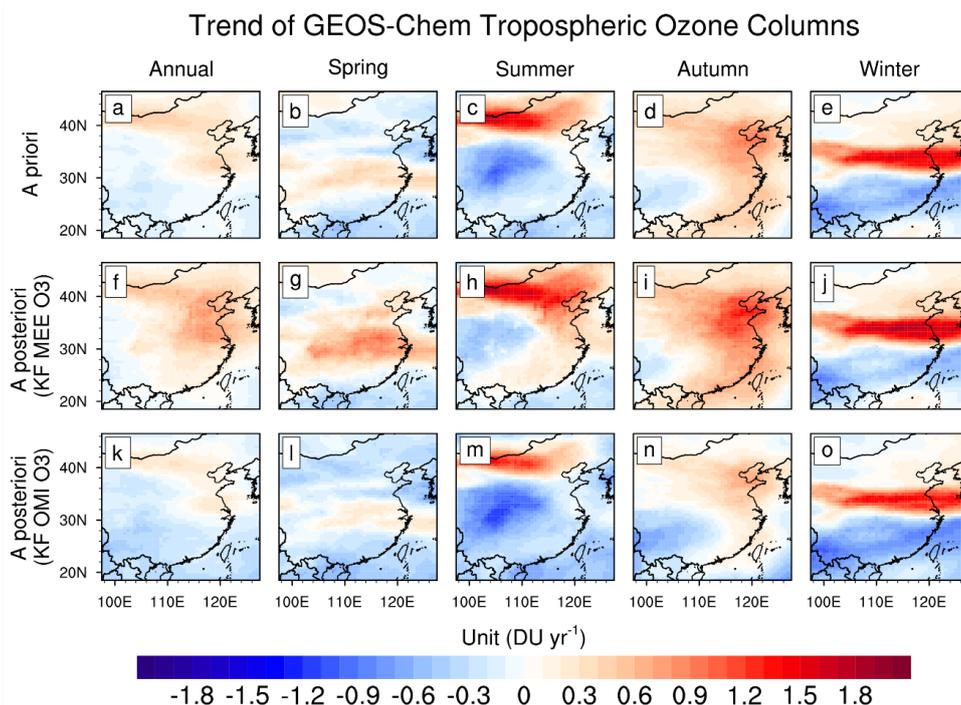

Fig. 12. Trends of tropospheric O₃ columns in 2015-2020 (annual and seasonal averages) from (A-E) GEOS-Chem a priori simulation; (F-J) assimilations of MEE surface O₃ observations; (K-O) assimilations of OMI O₃ observations.
