- 1 Abstract. NARCliM2.0 comprises two Weather Research and Forecasting (WRF) regional climate
- 2 models (RCMs) downscaling five CMIP6 global climate models contributing to the Coordinated
- 3 Regional Downscaling Experiment over Australasia at 20 km resolution, and south-east Australia at 4
- 4 km convection-permitting resolution. We first describe NARCliM2.0's design, including selecting
- 5 two, definitive RCMs via testing seventy-eight RCMs using different parameterisations for planetary
- 6 boundary layer, microphysics, cumulus, radiation, and land surface model (LSM). We then assess
- 7 NARCliM2.0's skill in simulating the historical climate versus CMIP3-forced NARCliM1.0 and
- 8 CMIP5-forced NARCliM1.5 RCMs and compare differences in future climate projections. RCMs
- 9 using the new Noah-MP LSM in WRF with default settings confer substantial improvements in
- 10 simulating temperature variables versus RCMs using Noah-Unified. Noah-MP confers smaller
- 11 improvements in simulating precipitation, except for large improvements over Australia's southeast
- 12 coast. Activating Noah-MP's dynamic vegetation cover and/or runoff options primarily improve
- 13 simulation of minimum temperature. NARCliM2.0 confers large reductions in maximum temperature
- 14 bias versus NARCliM1.0 and 1.5 (1.x), with small absolute biases of ~0.5K over many regions versus
- 15 over ~2K for NARCliM1.x. NARCliM2.0 reduces wet biases versus NARCliM1.x by as much as
- 16 50%, but retains dry biases over Australia's north. NARCliM2.0 is biased warmer for minimum
- 17 temperature versus NARCliM1.5 which is partly inherited from stronger warm biases in CMIP6

- 18 versus CMIP5 GCMs. Under shared socioeconomic pathway (SSP)3-7.0, NARCliM2.0 projects ~3K
- 19 warming by 2060-79 over inland regions versus ~2.5K over coastal regions. NARCliM2.0-SSP3-7.0
- 20 projects dry futures over most of Australia, except for wet futures over Australia's north and parts of
- 21 western Australia which are largest in summer. NARCliM2.0-SSP1-2.6 projects dry changes over
- 22 Australia with only few exceptions. NARCliM2.0 is a valuable resource for assessing climate change
- 23 impacts on societies and natural systems and informing resilience planning by reducing model biases
- 24 versus earlier NARCliM generations and providing more up-to-date future climate projections
- 25 utilising CMIP6.

# 28 **1. Introduction**

29	Climate projections are foundational to informing climate change mitigation and adaptation planning
30	at various spatial scales (IPCC, 2021). Regional climate models (RCMs) dynamically downscale
31	global climate models (GCMs) at ~100-200 km resolution to simulate higher resolution climate
32	projections that better resolve local-scale influences on regional climate, such as mountain ranges,
33	land-use variation, land-sea contrasts, and convective processes (Torma et al., 2015; Giorgi, 2019). As
34	such, whilst GCMs are the best tools for investigating climate at global scales, RCMs provide
35	improved guidance for climate policy at regional scale, which is the scale at which climate change
36	impacts are experienced (Hsiang et al., 2017).
37	The NARCliM programme (New South Wales and Australian Regional Climate Modelling) is
38	now in its third generation. Like its predecessors, NARCliM version 2.0 ('NARCliM2.0'), aims to
39	produce robust, detailed regional climate projections at spatial scales relevant for use in local-scale
40	climate change analysis. A key feature of all NARCliM generations is to simulate the climate over the
41	Coordinated Regional Downscaling Experiment (CORDEX)-Australasia domain, and a higher
42	resolution inner domain over southeast Australia via one-way nesting (Figure 1). With one-way
43	nesting the inner domain obtains its initial and lateral boundary conditions from the simulation over
44	CORDEX-Australasia. NARCliM1.0 simulated the climate of Australasia for three periods (1990-
45	2009, 2020-2039, 2060-2079) at 50 km resolution and southeast Australia at 10 km using three
46	configurations of the weather research and forecasting (WRF) RCM (Skamarock et al., 2008) to
47	downscale GCMs from Coupled Model Intercomparison Project phase three (CMIP3) under the SRES
48	A2 greenhouse gas (GHG) scenario (Evans et al., 2014). NARCliM1.5 used CMIP5 GCMs under
49	representative concentration pathways (RCP) 4.5 and 8.5 to simulate continuously for 1950-2100 on
50	the same grids as NARCliM1.0 using two of its RCMs (Nishant et al., 2021).
51	NARCliM2.0 aims to improve performance in simulating the Australian climate relative to
52	previous NARCliM generations with the goal of better informing community resilience to climate
53	change (New South Wales Government, 2022, 2023). All NARCliM projects include a bottom-up
54	design ethos involving multi-sectoral end-user engagement in specifying model requirements to
55	ensure model performance and outputs meet end-user needs. Key requirements from the NARCliM2.0
56	user-consultation include providing increased detail in climate simulations via higher resolution, and
57	improving the simulation of precipitation and temperature as these are fundamental inputs to climate
58	impact studies. Whilst NARCliM1.0 and 1.5 (1.x) confer the expected level of performance in
59	simulating the Australian climate (Di Virgilio et al., 2019; Evans et al., 2020b), recent technological
60	and scientific advancements mean that aspects of their performance might now be improved.
61	NARCliM1.x RCMs show widespread cold biases in maximum temperature exceeding -5K for some
62	RCMs. Conversely, minimum temperature is simulated more accurately with biases in the range of

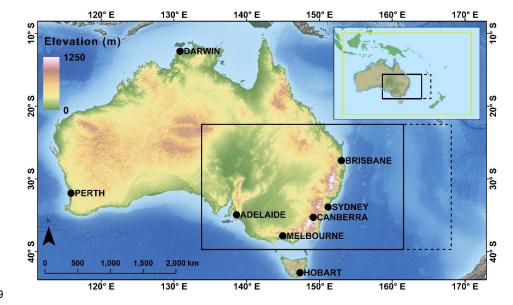

63	±1.5K. NARCliM1.x RCMs overestimate precipitation, particularly over Australia's socio-
64	economically important eastern seaboard (Di Virgilio et al., 2019).
65	As they are expensive to run from both computational and data storage perspectives, dynamical
66	downscaling projects like NARCliM2.0 use a subset of available GCMs as driving data, necessitating
67	careful model selection. Similarly, a large combination of different physical parametrisations
68	available for the WRF RCM enables many structurally different RCMs to be potentially used to
69	downscale GCMs. A key component of NARCliM2.0's design is testing the viability of alternative
70	RCM parameterisations via a three-phase approach, with each phase building on the preceding phase
71	to identify the RCM parameterisations that perform well during testing to meet NARCliM2.0's aim of
72	improving the simulation of Australia's climate. GCM and RCM statistical independence are also
73	sought to avoid creating a biased sample of climate change. Hence, the aims of this paper are to:
74	1) describe how and why NARCliM2.0 differs from its predecessors in terms of its design and
75	production processes, explaining the model test and evaluation approaches underlying its design
76	decisions. A key focus is on the design and testing of seventy-eight different WRF RCMs and their
77	evaluation to identify a subset of RCMs for use in NARCliM2.0;
78	2) characterise the performance improvements of CMIP6-NARCliM2.0 RCMs in simulating the
79	Australian climate relative to previous NARCliM generations by evaluating their skill in simulating
80	mean maximum and minimum temperature and precipitation versus observations;
81	and 3) summarise the climate projections produced by CMIP6-NARCliM2.0 and how these
82	differ from previous CMIP3-5-NARCliM generations.
83	The following section summarises the basic design features of each NARCliM generation;
84	section 3. describes NARCliM2.0's design process with a focus on its RCM physics testing, as well as
85	a brief overview of its production process; section 4. describes evaluation methods and metrics;
86	section 5. summarises the RCM physics test results; section 6. evaluates the performance of all
87	NARCliM models in simulating the recent Australian climate; section 7. provides an overview of their

88 future projections; and section 8. discusses key results and summarises this paper.

89

90 Figure 1. Model domains for NARCliM regional climate simulations. The southeast inner domain for
91 NARCliM2.0 is delineated with a solid black rectangle; the corresponding inner domain for NARCliM1.0 and
92 1.5 is delineated with a dashed black line. The elevated terrain of the Australian Alps which form part of the
93 Great Dividing Range is in eastern Australia. Inset shows the CORDEX-Australasia outer domain.

# 94 2. Three generations of NARCliM: model overviews

95 The design of NARCliM1.0 is described in Evans et al. (2014); NARCliM1.5 used the same design approach but used CMIP5 rather than CMIP3 GCMs. All generations of NARCliM use different 96 versions of the WRF model (Skamarock et al., 2008) to perform dynamical downscaling of GCMs 97 since the WRF model goes through regular updates. The southeast Australian inner domain captures 98 99 five of Australia's eight capital cities (Figure 1) and over 75% of the Australian population 100 (Australian Bureau Statistics, 2024). Additionally, the inner domain captures coastal regions that are 101 characterised by topographic complexity and land-use class variation. Regions east of the Great 102 Dividing Range mountains in southeast Australia (Figure 1) show different responses to oceanic 103 climate modes compared to inland semi-arid regions (Murphy and Timbal, 2008) and are impacted by 104 events such as rapidly developing storms, including east coast lows (Pepler and Dowdy, 2021). Such 105 atmospheric processes are not adequately resolved by GCMs due to coarse resolutions (Di Virgilio et 106 al., 2022; Grose et al., 2020). 107 NARCliM2.0 encompasses several design advancements over its predecessors (Table 1). 108 NARCliM2.0 RCMs have a 20 km resolution CORDEX-Australasia domain (versus 50 km) and 4 km (versus 10 km) domain over southeast Australia and use 45 (versus 30) vertical levels. The aim of 109

<ul> <li>convection-permitting (Kendon et al., 2021; Lucas-Picher et al., 2021). Hence, whilst the 20 km-</li> <li>resolution outer domain uses cumulus parametrisation, simulations over the 4 km domain do not use</li> <li>cumulus parametrisation. NARCliM2.0 also includes a new collaboration with the Western Australian</li> <li>government, with separate 4 km simulations being performed over south-west and north-west Western</li> <li>Australia (not shown in Figure 1) as part of the Western Australian climate science initiative (DWER,</li> <li>2023). Boundary conditions derived from the 20 km NARCliM2.0 CORDEX Australasia domain are</li> <li>used to drive these simulations. Additional major differences in model setup for NARCliM2.0</li> <li>include:</li> <li>NARCliM1.0 RCMs use different parameterisations for planetary boundary layer (PBL)</li> <li>physics, surface physics, cumulus physics, land surface model (LSM), and radiation (Evans et al., 2014). These RCM parameterisations for NARCliM2.0 differ to those of NAR-</li> <li>CliM1.x (see sect. 3).</li> <li>NARCliM2.0 increases the number of driving GCMs to 5 and simulates for a wider range of plausible future climates via three shared socioeconomic pathways (SSP). SSP1-2.6 is selected as a low GHG scenario envisaging a future climate with CO<sub>2</sub> emissions cut to net zero by around 2075 and warming held to below 2<sup>°</sup>C by 2100; SSP2-4.5 estimates projected warming under a 'middle of the road' scenario where temperatures increase to ~2.7<sup>°</sup>C by 2100; and SSP3-7.0 is a high GHG scenario which assumes warming of ~4<sup>°</sup>C by 2100 (IPCC, 2021).</li> <li>Urban physics is activated in NARCliM2.0 (WRF setting: sf_urban_physics=1) to represent surface energy balance in urban areas via a single layer urban canopy model (Kusaka and Kimura, 2004).</li> <li>Input of different aerosol species is activated for the RCM radiation scheme using the Tegen et al. (1997) climatology available in WRF (aer_opt=1). This aerosol forcing is the same for all GCMs, and not model-specific.</li> <l< th=""><th>110</th><th colspan="5">increasing the resolution of this inner domain from 10 km to 4 km is to render these simulations</th></l<></ul>	110	increasing the resolution of this inner domain from 10 km to 4 km is to render these simulations					
<ul> <li>cumulus parametrisation. NARCliM2.0 also includes a new collaboration with the Western Australian government, with separate 4 km simulations being performed over south-west and north-west Western Australia (not shown in Figure 1) as part of the Western Australian climate science initiative (DWER, 2023). Boundary conditions derived from the 20 km NARCliM2.0 CORDEX Australasia domain are used to drive these simulations. Additional major differences in model setup for NARCliM2.0 include:</li> <li>NARCliM1.0 RCMs use different parameterisations for planetary boundary layer (PBL) physics, surface physics, cumulus physics, land surface model (LSM), and radiation (Evans et al., 2014). These RCM parameterisations were also used for NARCliM1.5. Owing to the project aims stated above, RCM parameterisations for NARCliM2.0 differ to those of NAR-CliM1.x (see sect. 3).</li> <li>NARCliM2.0 increases the number of driving GCMs to 5 and simulates for a wider range of plausible future climates via three shared socioeconomic pathways (SSP). SSP1-2.6 is selected as a low GHG scenario envisaging a future climate with CO<sub>2</sub> emissions cut to net zero by around 2075 and warming held to below 2°C by 2100; SSP2-4.5 estimates projected warming under a 'middle of the road' scenario where temperatures increase to ~2.7°C by 2100; and SSP3-7.0 is a high GHG scenario which assumes warming of ~4°C by 2100 (IPCC, 2021).</li> <li>Urban physics is activated in NARCliM2.0 (WRF setting: sf_urban_physics=1) to represent surface energy balance in urban areas via a single layer urban canopy model (Kusaka and Kimura, 2004).</li> <li>Input of different aerosol species is activated for the RCM radiation scheme using the Tegen et al. (1997) climatology available in WRF (aer_opt=1). This aerosol forcing is the same for all GCMs, and not model-specific.</li> <li>The eastern boundary of the NARCliM2.0 inner domain is located further westward relative</li> </ul>	111	convection-permitting (Kendon et al., 2021; Lucas-Picher et al., 2021). Hence, whilst the 20 km-					
<ul> <li>government, with separate 4 km simulations being performed over south-west and north-west Western Australia (not shown in Figure 1) as part of the Western Australian climate science initiative (DWER, 2023). Boundary conditions derived from the 20 km NARCliM2.0 CORDEX Australasia domain are used to drive these simulations. Additional major differences in model setup for NARCliM2.0 include:</li> <li>NARCliM1.0 RCMs use different parameterisations for planetary boundary layer (PBL) physics, surface physics, cumulus physics, land surface model (LSM), and radiation (Evans et al., 2014). These RCM parameterisations were also used for NARCliM1.5. Owing to the project aims stated above, RCM parameterisations for NARCliM2.0 differ to those of NAR-CliM1.x (see sect. 3).</li> <li>NARCliM2.0 increases the number of driving GCMs to 5 and simulates for a wider range of plausible future climates via three shared socioeconomic pathways (SSP). SSP1-2.6 is selected as a low GHG scenario envisaging a future climate with CO<sub>2</sub> emissions cut to net zero by around 2075 and warming held to below 2°C by 2100; SSP2-4.5 estimates projected warming under a 'middle of the road' scenario which assumes warming of ~4°C by 2100 (IPCC, 2021).</li> <li>Urban physics is activated in NARCliM2.0 (WRF setting: sf_urban_physics=1) to represent surface energy balance in urban areas via a single layer urban canopy model (Kusaka and Kimura, 2004).</li> <li>Input of different aerosol species is activated for the RCM radiation scheme using the Tegen et al. # 139 3. NARCliM2.0 design and production process overview

140 The NARCliM2.0 design and production processes are summarised below in reference to Figure 2.

141 The design process is an adaptation of that introduced in Evans et al. (2014). Two companion

142 manuscripts describe elements shown in Figure 2, and which are therefore only summarised briefly in

143 this manuscript. Di Virgilio et al. (2022) describes the CMIP6 GCM selection process summarised in

Box 2, and Di Virgilio et al. (in review) describes the ERA5 evaluation undertaken in Boxes 5 and 6.

#### 145 I. Design Phase:

146	i)	Box 1: model design requirements are identified via consultation between NARCliM2.0
147		modelling groups and multi-sectoral end-users, as well as adherence to CORDEX-CMIP6
148		design requirements (WCRP, 2020).

149	ii)	Box 2: NARCliM1.x selected driving CMIP3-5 GCMs (respectively) via literature review
150		of existing GCM evaluations. During NARCliM2.0 design, there were no pre-existing
151		comprehensive evaluations of individual CMIP6 GCMs for the Australian region, includ-
152		ing assessments of climate change signals and GCM statistical independence. Hence, an
153		evaluation and selection of CMIP6 GCMs was conducted (see Di Virgilio et al. 2022).
154		This evaluation selected five GCMs to force two NARCliM2.0 RCMs (see sect 3.2 and
155		3.4). The relative contribution to uncertainty/variation in climate projections can be larger
156		for GCMs than for RCMs (e.g. Lee et al., 2023).
157	iii)	Box 3: a new WRF RCM multi-physics test ensemble is created for NARCliM2.0: RCM
158		physics testing is conducted via a three-phase approach, with each phase building on the
159		findings of the preceding phase to identify the RCM parameterisations that perform well
160		during testing with the aim of improving the simulation of the Australian climate. In this
161		way, RCMs are parameterised with different physics settings via each test phase, system-
162		atically removing poor performing options while facilitating the fine tuning and im-
163		provement of the parameterisations that perform well during testing to build a total en-
164		semble size of seventy-eight structurally different test RCMs. The performances of the
165		different test RCM configurations are evaluated, ultimately selecting a subset of seven
166		RCMs for subsequent downscaling of ERA5 reanalysis and comprising the CORDEX
167		evaluation experiment.
168	iv)	Boxes 4-6: These seven RCMs are used to downscale ERA5 reanalysis over the 20 km
169		and 4 km domains for 1979-2020. Evaluating these ERA5-forced simulations informs se-
170		lection of two 'production' RCMs for CMIP6-forced downscaling (see sect. 3.4 and Di
171		Virgilio et al. in review).
172	II. Produc	ction Phase:
173	i)	Boxes 7-8: CMIP6 GCM data are pre-processed to create initial and boundary conditions
174	,	to drive simulations for the historical (1950-2014) and SSP experiments (2015-2100). A
175		code repository used for this GCM preprocessing is available at
176		https://bitbucket.org/oehcas/narclim2-
177		0 design and evaluation 2024 support materials/src/main/ within the
178		WRF/repo_snapshots subdirectory. Quality assurance/quality control (QA/QC) is per-
179		formed on these data before initiating the simulations (e.g. variables are checked to con-
180		firm data do not contain significant outliers across ensemble members).
181	ii)	Boxes 9-11: the 151-year CMIP6-forced NARCliM2.0 RCM simulations are run using
182		National Computing Infrastructure at Canberra, Australia (NCI, https://nci.org.au/). File
183		integrity verification and QA/QC are performed on each year of raw WRF output
184		throughout the simulation lifecycle and prior to post-processing to CORDEX-compliant

8

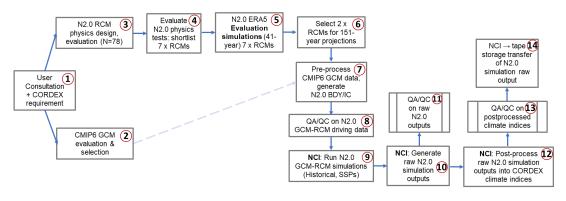

185		format climate variables. QA/QC tests include calculating the minimum, maximum, mean
186		and standard deviation for key variables over consecutive periods of six days. Variables
187		are categorised as either normally distributed or otherwise. Normally distributed variables
188		(e.g. surface temperature) are deemed potentially erroneous if their minima/maxima are
189		greater than five standard deviations away from the global mean of the relevant statistic
190		of the rolling six-day period. Non-normally distributed variables (e.g. snow depth and
191		precipitation) are checked for global minima and maxima only.
192	iii)	Boxes 12-13: after each year of simulation raw output is generated, their post-processing
193		is initiated to produce CORDEX CORE, Tier 1 and Tier 2 variables (WCRP, 2022). A
194		statistical QA/QC process is automatically applied to each year of post-processed
195		CORDEX CORE variables as they are generated throughout the simulations. QA/QC
196		tests include:
197		<ul> <li>Check for presence of missing values.</li> </ul>
198		• Check that all values are within realistic ranges for minima and maxima.
199		• Check minima and maxima are not equal at any timestep with exceptions (e.g.
200		snow depth which can be zero everywhere in the outer domain).
201		• Check that changes over time are within realistic ranges (i.e. assess temporal gra-
202		dients).
203		<ul> <li>Check that changes between neighbouring data points are within realistic ranges</li> </ul>
204		(i.e. assess spatial gradients).
205		<ul> <li>Check the number of grid cells with NaN (non-numerical) values do not exceed</li> </ul>
206		the threshold set for the variable.
207		Reasonable ranges for variables are determined using a series of threshold values that are
208		based on historical records and/or empirical analysis. QA/QC computer scripts generate
209		'exceedance files' which output every data point that surpasses the threshold values, and
210		these exceedance files are then manually reviewed to determine whether an issue is a true
211		or false positive, etc.
212	iv)	Box 14: Once each year of WRF raw files are post-processed, raw files are transferred to
213		a tape facility for long-term storage.

9

**Figure 2.** Simplified overview of NARCliM2.0 (N2.0) design and production processes. ERA5 = ECMWF

217 Control; NCI = National Computing Infrastructure (high performance computer used for N2.0 production

218 simulations).

214

219 These model design and production stages are now described in more detail:

## 220 3.1 Model evaluation and selection

221 Practical constraints such as available compute and data storage resources enforce an upper limit on 222 GCM-RCM ensemble size. Thus, NARCliM2.0 uses a subset of available CMIP6 GCMs and WRF 223 RCM configurations, necessitating careful GCM and RCM selection to create a subset of GCM-RCMs that provide robust climate simulations whilst also adequately sampling model uncertainty. In 224 225 selecting a subset of GCMs and RCMs for dynamical downscaling, it is desirable to reject models that perform consistently poorly relative to their peers in simulating the current climate, as this provides 226 227 lower confidence in the projected change (Evans et al., 2020b; Di Virgilio et al., 2022; Grose et al., 228 2023). Furthermore, the modelled climate space sampled is reduced when selecting a subset of GCMs, 229 which can create a biased view of the climate, as well as the plausible change in climate. Care must 230 therefore be taken to ensure that the subset of models used for downscaling are representative of the 231 full range of possible climates, and that model errors are uncorrelated, i.e., that models are statistically 232 independent. The steps taken to evaluate and select GCMs and RCMs for NARCliM2.0 are described 233 next.

## 234 3.2 CMIP6 GCM evaluation

235 A three-phase process was used to evaluate individual CMIP6 GCMs (for further details see Di

**236** Virgilio et al. 2022):

#### 3.2.1 CMIP6 GCM Performance 237

238	The performances of individual CMIP6 GCMs in simulating the Australian climate were assessed
239	with respect to climate means, extremes, climate modes, and daily climate variable distributions. A se
240	of GCMs that performed consistently poorly across the variables and statistics considered were
241	identified. These models, as well as those with insufficient data to enable dynamical downscaling
242	using the WRF RCM, were excluded from further evaluation leaving 27 GCMs for subsequent
243	assessment.

#### 244 3.2.2 CMIP6 GCM Independence

- 245 The retained 27 GCMs were subjected to the Bishop and Abramowitz (2013) and Herger et al. (2018)
- independence analyses (see sect. 4.4). The GCMs were then ranked according to their relative level of 246
- 247 statistical independence.

#### 248 3.2.3 Sampling CMIP6 GCM Climate Change Spread

- 249 For climate change risk assessments, climate projections should reflect as much of the range of
- plausible future climate changes as possible (Whetton and Hennessy, 2010). The subset of CMIP6 250
- 251 GCMs selected for NARCliM2.0 spanned a wide range of future changes in annual mean temperature
- 252 and precipitation. Climate change signals were calculated for 2080-2099 minus 1995-2014 for the
- 253 Australian continent and south-east Australia under SSP3-7.0 (for the latter, see Figure 3). The GCM
- 254 independence rankings were placed within this climate change space, with higher independence
- 255 rankings viewed as favourable, along with consideration of the following criteria:
- A balanced range of GCM Equilibrium Climate Sensitivities (ECS) were sampled. ECS is the 256 i) 257 long-term increase in global mean surface air temperature in response to the radiative forcing 258 caused by a doubling of pre-industrial CO<sub>2</sub> concentrations. ECS is related to global tempera-259 ture change, not just changes over Australia, however, it correlates strongly with regional warming. Around one third of CMIP6 GCMs show ECS values higher than the upper end of 260 261 the likely range of 2.5°C to 4°C (IPCC, 2021). An upper range of > ~5°C cannot be ruled out
- 262 (Meehl et al., 2020; Bjordal et al., 2020; Sherwood et al., 2020).
- 263 ii) Some CMIP6 GCMs that are favourable in terms of model performance and independence
- 264 could not be selected as input to WRF for NARCliM2.0 owing to insufficient data availability
- 265 for key variables/variable, where ideally, WRF requires sub-daily data for the variables
- 266 shown in Supporting Information, Table S1.

267 As a result of the above process, the five CMIP6 GCMs listed in Table 2 are selected to force

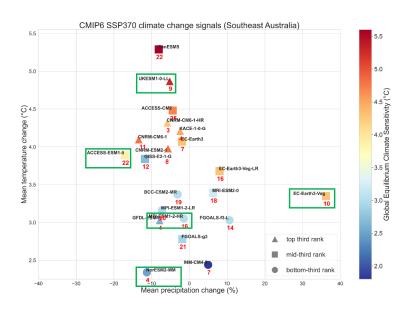

268 NARCliM2.0 RCMs.

CMIP6 GCM	Institution	Variant/Run	Atmosphere lat/lon grid (°)
ACCESS-ESM1-5	CSIRO	r6i1p1f1	1.2  imes 1.8
EC-Earth3-Veg	EC-EARTH consortium	rli1p1f1	0.7 imes 0.7
MPI-ESM1-2-HR	Max Planck Institute for Meteorology (MPI)	r1i1p1f1	~0.9
NorESM2-MM	Norwegian Climate Centre	r1i1p1f1	0.9  imes 0.9
UKESM1-0-LL	UK Met Office and NERC research centres	r1i1p1f2	1.3  imes 1.9

#### 269 Table 2. Basic details of the CMIP6 GCMs used for NARCliM2.0 simulations.

270 271

Figure 3. CMIP6 GCM climate change signals (2080-2099 versus 1995-2014) over south-east Australia for the
subset of GCMs retained following the model performance evaluation in Di Virgilio et al. (2022), and that
simulated at least monthly mean near surface air temperature and precipitation for the SSP-3.70 scenario. Boxed
GCMs are selected to force NARCliM2.0 RCMs. Marker shapes indicate overall GCM performance; markers
are coloured according to their global equilibrium climate sensitivity (ECS) values; Red numbers represent the
smallest Herger Method 1 set for that GCM.

## 277 3.3 NARCliM2.0 RCM physics testing

278 The NARCliM2.0 RCM physics testing aims to identify and exclude RCMs that perform consistently

- 279 poorly in simulating the southeast Australian climate and to select RCMs that have high statistical
- 280 independence. The selection of RCMs in NARCliM2.0 involves the creation of a multi-physics
- 281 ensemble where each RCM uses different physical parametrisations for PBL, microphysics, cumulus,
- 282 radiation, and LSM. This enables many structurally different RCMs to be constructed and tested. In

283 NARCliM1.0, 36 WRF RCM configurations were designed, tested, and evaluated (Evans et al. 2014). 284 NARCliM2.0 physics testing assesses 78 RCM configurations which are progressively tested via three 285 phases, where each test phase is informed by the outcomes of the preceding phase to systematically 286 remove poor performing RCM options while facilitating the selection of parameterisations that 287 perform well during testing. The N=36 RCMs tested for NARCliM1.0 were evaluated based on eight 288 representative storm event simulations each of two-weeks duration (Evans et al. 2014). NARCliM2.0 289 physics simulations were run over an entire annual cycle (2016) with a two-month spin up period commencing 1 November 2015. Australia experienced a range of weather extremes during 2016 290 291 driven by a range of climatic influences making 2016 a suitable target year (Bureau of Meteorology, 292 2017). Whilst assessing RCMs for an entire year improves on assessing for discrete storm events as 293 per physics testing for NARCliM1.0, it was not feasible to run a large RCM physics ensemble for a 294 longer duration. Initial and boundary conditions for all phases of the NARCliM2.0 RCM physics test 295 simulations were derived from the ERA-Interim reanalysis data set (Dee et al., 2011). ERA-Interim 296 was used because ERA5 was not available at the time. The three phases of NARCliM2.0 physics 297 testing are as follows:

#### 298 3.3.1 Phase I (N=36)

Thirty-six RCMs were evaluated in Phase I. One radiation scheme (RRTMG) is tested for both long 299 300 and short-wave radiation (it is held fixed for all RCMs), whereas physics settings for PBL, 301 microphysics, cumulus, and LSM are varied. Of the 36 simulations, 18 used the Noah-Unified LSM, 302 whilst the remainder used Community Land Model version 4.0 (CLM4). The physics options tested 303 are listed in Table 3, where these were selected based on literature review. Each physics test 304 simulation is denoted by a 12-digit identifier which comprises 6 pairs of digits, with each pair 305 corresponding to the choice of a specific physics option as specified in the WRF namelist.input file. 306 These pairs of digits follow the order: planetary boundary layer (pbl) | cloud microphysics (mp) | 307 cumulus convection (cu) | shortwave radiation (sw) | longwave radiation (lw) | LSM (sf) and correspond to the WRF namelist options shown in Table 3. For example, the simulation 308 '050601040402' is interpreted as:  $05 \mid 06 \mid 01 \mid 04 \mid 04 \mid 02$  and denotes that this simulation uses the 309 310 following physics settings:

bl\_pbl\_physics= 05 (MYNN2)mp\_physics= 06 (WSM6)cu\_physics= 01 (Kain-Fritsch)ra\_sw\_physics= 04 (RRTMG)ra\_lw\_physics= 04 (RRTMG)sf\_surface\_physics= 02 (Noah Unified)

- 311 The complete set of WRF RCM configurations tested in Phase I is shown in Supporting Information
- 312 Table S2.
- **Table 3.** Physics options used in phase I (N=36) tests.

#### 314 3.3.2 Phase II (N=60): additional LSM and radiation scheme tests

Phase I RCMs using CLM4.0 were omitted from further testing because they did not consistently im-315 316 prove performance in simulating the Australian climate relative to RCMs using Noah-Unified. In ad-317 dition, RCMs using CLM4.0 had increased simulation times (by approximately twice when compared 318 to Noah-Unified). Hence, Phase II focuses exclusively on further testing of the RCM configurations 319 that used the Noah-Unified LSM. 320 The physics settings tested in Phase II are an alternative LSM to Noah-Unified (Noah Multi-Parameterisation; 'Noah-MP', Niu et al., 2011) and New Goddard radiation. Owing to time/resource 321 322 constraints, testing all eighteen Phase I RCMs using Noah-Unified was not feasible. To reduce the 323 number of RCMs for further testing, the worst-performing Noah-Unified based RCM configurations 324 identified in Phase I were excluded. The N=18 RCMs using Noah-Unified are listed along with their 325 overall performance total scores in Table 4 where the lowest scores under 'Rank totals' indicate the 326 RCMs that overall perform relatively well versus their peers (see sect. 4 Evaluation Methods). Note 327 that the 'Overall rank' denotes the RCMs' relative ranking among all Phase I RCMs. There is a sharp 328 reduction in rank totals for RCMs #13-18 inclusive, relative to RCMs #1-12. Therefore, RCMs #13-329 18 are excluded from further testing, and RCMs #1-12 are retained. Table 4. RCM physics combination ranks of the Phase I, N=18 Noah Unified (NU) based RCMs. 330 331 Scores/ranks are based on model bias and root mean square error for annual and seasonal precipita-332 tion, minimum temperature, maximum temperature, climate extremes (wettest and hottest days), and

333 Perkins Skill Scores (see sect. 4). RCMs #1-12 are selected for further testing.

RCM		Physics combination					Rank	Overall rank in
#	RCM ID	PBL	PBL MP		SW/LW	LSM	total	N=36 Phase I
1	070801040402	ACM2	Thom	KF	RRTMG	NU	484	1

16	050602040402	MYNN2	WSM6	BMJ	RRTMG	NU	811	31
17	010806040402	YSU	Thompson	Tiedtke	RRTMG	NU	830	34
18	050806040402	MYNN2	Thompson	Tiedtke	RRTMG	NU	857	35

334 This gives two sets of physics combinations for additional testing: 1) one replaces only RRTMG

(|04|04|) for short and longwave radiation with New Goddard (|05|05|) making no other changes; and

336 2) RRTMG radiation is retained, but Noah-MP (|04|) replaces Noah-Unified (|02|). This creates an

additional 24 RCM configurations for assessment, bringing the total RCMs tested to 60. Although

338 Noah-MP has several parameter options, Phase II uses its default settings.

#### 339 3.3.3 Phase III (N=78): parameterising Noah-MP

340 Phase II shows that RCM performance using New Goddard radiation is generally inferior to the same

341 RCMs using RRTMG (see sect. 5. RCM Physics test results). Consequently, RRTMG radiation is re-

342 adopted for Phase III. Conversely, a general performance improvement is conferred by using Noah-

343 MP over Noah-Unified (sect. 5). Given this performance improvement using Noah-MP with default

344 settings, Phase III assesses RCM performances using specific parameter settings for Noah-MP.

345 Noah-MP provides a 'dynamic vegetation cover' model option (referred to as dynamic vege-

tation in the WRF users' guide) (Niu et al., 2011). When deactivated (the default), monthly leaf area

347 index (LAI) is prescribed for various vegetation types and the greenness vegetation fraction (GVF)

348 comes from monthly GVF climatological values. Conversely, when dynamic vegetation cover is acti-

- 349 vated, LAI and GVF are calculated using a dynamic leaf model. We clarify here that dominant plant-350 functional types do not change when using this option, but only the LAI and GVF, i.e. only the 351 amount of green cover changes. 352 Noah-MP also provides several options for modelling surface run-off and groundwater pro-353 cesses including a TOPMODEL (TOPography based hydrological MODEL)-based surface runoff 354 scheme and a simple groundwater model (SIMGM; Niu et al., 2011). Some studies have shown using 355 this option improves modelling of soil moisture (e.g. Zhuo et al., 2019). Thus, three new sets of phys-356 ics configurations are tested using Noah-MP where default options for specific settings are changed as 357 follows: 358 1. activate dynamic vegetation cover (dveg=2 in the WRF namelist); no other changes. 359 2. activate TOPMODEL runoff with simple groundwater (opt\_run=1); no other changes. 360 3. activate both dynamic vegetation and TOPMODEL runoff with simple groundwater, no other 361 changes.
- As above, the worst performing RCMs in Phase II are excluded from Phase III testing. Based on the RCM configuration performance rankings (Table 5), there is a sharp reduction in performance starting from RCM #7 inclusive. Therefore, RCMs #7-12 are excluded from further testing. Phase III thus comprises 18 new test simulations (sets 1-3 each comprising 6 RCMs) bringing the total RCMs tested to N=78. Phase III physics tests are denoted using the same RCM identification schemes distinguished by appending 'set\_1', 'set\_2', 'set\_3' to identifiers.

368 Table 5. RCM physics combination ranks of the Phase II Noah-MP RCMs. Scores/ranks are based on model

369 bias and root mean square error for annual and seasonal precipitation, minimum temperature, maximum temper-

ature, climate extremes (wettest and hottest days), and Perkins Skill Scores (see sect. 4).

No.	Physics combination	Rank total
1	50801040404	721

12	10602040404	1264

#### 371 3.3.4 Shortlisting Physics Test RCMs for ERA5-NARCliM2.0 evaluation simulations

372 Considering the complete NARCliM2.0 N=78 physics test ensemble, to identify physics test RCMs

that perform poorly overall, RCMs are eliminated if they are in the lowest 1/3 for RCM performance

374 ranks for any of maximum temperature, minimum temperature, precipitation, or for the overall model

375 performance rank across these variables (see sect. 5. RCM Physics test results). Under this scheme, 20

376 RCMs remain. The independence measures are then applied to the remaining 20 RCMs to choose a

377 final subset of 7 RCMs for ERA5-forced evaluation simulations (see sect. 3.4). The ensemble size

378 limit of N=7 is determined by available compute resources. These 7 candidate RCMs are assessed for

379 potential use in the CMIP6 GCM-forced downscaling phase of NARCliM2.0 (sect. 3.4 and Di Virgil-

380 io et al. in review).

#### 381 3.4 CORDEX ERA5-NARCliM2.0 evaluation simulations

NARCliM1.x performed production climate simulations using a two-phase process. Its RCM physics 382 383 testing selected definitive 'production-grade' RCMs which were then used to downscale both reanalysis data and CMIP3/5 GCMs. In contrast, for NARCliM2.0, as described above the N=78 RCM phys-384 ics testing culminates in shortlisting 7 'production-candidate' RCMs which are used to downscale the 385 386 ERA5 reanalysis for 42-years (1979-2020). This enables assessment of shortlisted RCM performances 387 over a climatological period rather than the single year (2016) of the physics testing, which helps as-388 certain that performance differences between shortlisted RCMs are robust across a multi-decadal 389 timescale capturing climatologically diverse years. The aim is that two definitive production-grade 390 RCMs can be selected for CMIP6-forced downscaling from these ERA5-forced CORDEX 'evalua-391 tion' simulations. Thus, the seven ERA5-NARCliM2.0 RCMs were driven by ERA5.0 boundary con-392 ditions for January 1979 to December 2020 using the model and nested domain setups described 393 above for NARCliM2.0. The skill of these RCMs in simulating the recent Australian climate was as-394 sessed as follows (see Di Virgilio et al. in review): annual and seasonal means were calculated for 395 maximum and minimum temperature and precipitation using monthly means for temperature varia-396 bles, and the monthly sum for precipitation. Extremes of maximum temperature and precipitation (99th 397 percentiles) and extreme minimum temperature (1<sup>st</sup> percentile) were calculated using daily data. RCM 398 performances in reproducing observations over these timescales were assessed by calculating model 399 outputs minus observations (i.e. model bias), and the RMSE of modelled versus observed fields. RCM 400 skill in simulating distributions of observed variables was assessed by comparing the probability den-401 sity functions (PDFs) for daily mean observations versus those of the RCMs. The ultimate outcome of 402 these ERA5-forced simulations and their evaluation is the selection of two RCM configurations, R3 403 and R5 to run the CMIP6-forced phase of NARCliM2.0, see Di Virgilio et al. (in review) for further 404 details on the evaluation methods and results. Supporting Information Figure S1 shows the WRF 405 namelist settings for the R3 and R5 RCMs (see also sect. 9. Code Availability).

#### 406 3.5 CORDEX CMIP6-forced NARCliM2.0 simulations

- 407 The ideal CMIP6 GCM variables and their frequencies required to run the WRF RCM are listed in 408 Table S1. A minority of variables in Table S1 are not available at sub-daily frequencies for every tar-409 get GCM. This necessitates assumptions/data proxies to be made. For instance, soil moisture and soil 410 temperature variables were unavailable for some selected GCMs; hence, surrogate data, such as sur-411 face temperature, were used for initialisation (noting that soil data are only used by the RCM at ini-412 tialisation). In these cases, we investigated how long it took for uncertainty in the initial conditions to 413 disappear from the WRF output by analysing the regionally averaged soil moisture time series. The 414 data were regionalised according to the four Australian Natural Resource Management (NRM) re-415 gions / climate zones (Supporting Information Figure S2) which are broadly aligned with climatologi-416 cal boundaries (Fiddes et al., 2021) and with the IPCC reference regions (Iturbide et al., 2020). Time series plots (Figure S3) show that soil moisture equilibrates to be within a normal range following 417 418 initialisation, indicating that the 12-month spin-up year (1950) is sufficient to account for the assump-419 tions made at model initialisation. 420 Boundary and initial conditions were prepared using selected GCM data to run the 151-year GCM-driven simulations using WRF version 4.1.2. The GCM-driven simulations were run and com-421 422 pleted using the pre-defined RCM settings for two RCM configurations using the WRF namelists in 423 Supporting Information Figure S1 (see also sect. 9. Code Availability). A cold restart was performed on the last Historical experiment year (2014), thus enabling the SSP1-2.6 and SSP3-7.0 experiments 424 425 to be run for 2015-2100 concurrently with the Historical experiment. The 2014 cold start year is even-
- 426 tually overwritten by Historical runs initiated in 1950.
- 427 **4. Evaluation methods**
- This section largely focuses on the methods and metrics used for the NARCliM2.0 RCM physics testing. Overviews of the methods and metrics for CMIP6 GCM evaluation and selection and assessments
  of the ERA5-forced evaluation simulations are provided above, with further information on these
  available in Di Virgilio et al. (2022) and Di Virgilio et al. (in review).

#### 432 4.1 Observations

433 Australian Gridded Climate Data (AGCD version 1.0; Evans et al., 2020a) are the observational data

434 used to evaluate the NARCliM2.0 RCM physics test RCMs. These daily gridded data for maximum

- 435 and minimum temperature and precipitation are obtained from an interpolation of station observations
- 436 across Australia. AGCD data are on a regular WGS84 grid with a grid-averaged resolution of 0.05°.
- 437 For the NARCliM2.0 RCM physics tests, the AGCD data were re-gridded to correspond with the
- 438 RCM data from the inner domain on their native grids using a conservative area-weighted re-gridding

- 439 scheme. All data (RCM and AGCD) were restricted to a common extent contained within the inner
- 440 domain over southeast Australia, and a land mask was applied so that statistics were computed using
- 441 only land pixels. Treatment of AGCD for the CMIP6 GCM evaluation and the ERA5-NARCliM2.0

442 RCM evaluation is described in Di Virgilio et al. (2022) and Di Virgilio et al. (in review), respective-

443 ly.

### 444 4.2 Methods and metrics: phase I-III physics tests

- 445 RCM performances in reproducing observations for daily maximum and minimum temperature and daily precipitation were assessed by calculating the model bias, i.e. model outputs minus AGCD, and 446 the RMSE of modelled versus observed fields. Model biases and RMSEs were calculated at annual 447 448 and seasonal timescales. The model representations of the hottest and the wettest day on an annual 449 time scale over the study region were also compared with AGCD. PDFs were calculated for each var-450 iable using daily data. The Perkins skill score (PSS) (Perkins et al., 2007) was calculated to assess the 451 overall degree of overlap between modelled and observed distributions, with PSS = 1 indicating that 452 distributions overlap perfectly. 453 To identify the overall performances of the RCM configurations, the RCMs are ranked based 454 on the bias and RMSE for all variables and seasons, the annual PSS, as well as the bias and RMSEs 455 for the maximum temperature and precipitation extremes. These ranks are then summed with the low-
- 456 est totals indicating the best performing RCM configurations overall.

#### 457 4.3 CMIP6 GCM and ERA5-NARCliM2.0 evaluations

458 Overviews of the evaluation methods and rationale for these components of NARCliM2.0 design have

been provided above. For further details on methods and results on the CMIP6 GCM evaluation and

the ERA5-NARCliM2.0 RCM evaluation, see Di Virgilio et al. (2022) and Di Virgilio et al. (in re-

461 view), respectively.

#### 462 **4.4 Independence assessments**

463 We used the method of Bishop and Abramowitz (2013) as one of two methods of assessing the inde-

464 pendence of physics test RCMs and the target CMIP6 GCMs under evaluation for use in NAR-

465 CliM2.0. This approach uses the covariance in model errors as the basis to define model dependence;

466 specifically, independence coefficients are derived from the error covariance matrix of the RCMs or

467 GCMs. Model independence is quantified using the correlation of model errors. For the physics test

468 RCMs, errors are computed by comparing the climatology of maximum and minimum temperature

469 and precipitation over the south-east Australia inner domain for 2016 with corresponding AGCD ob-

470 servations. The same calculation is performed for the CMIP6 GCMs, except for the Australian conti-

471 nent. Daily timeseries of precipitation, maximum and minimum temperature are calculated individual-

472 ly for each RCM and for AGCD. The simulated and observed daily timeseries of each variable are 473 then normalised by the standard deviation of the corresponding observed variable. These normalised 474 variables are concatenated for each RCM (GCM) and AGCD. An anomaly time series for each grid 475 cell is then produced. These time series are used to create a 'model error covariance matrix' contain-476 ing the errors for all RCMs (GCMs). The coefficients of a linear combination of the RCMs (GCMs) 477 that optimally minimises the mean square error depends on both model performance and model dependence (Bishop and Abramowitz, 2013). The result of this minimisation problem is written in terms 478 479 of the covariance matrix. The magnitude of coefficients assigned to each RCM (GCM) reflects a 480 combination of their performance and independence. Highly independent models have different errors 481 when simulating the recent climate. Models with the largest coefficients have the most independent 482 errors versus observations. 483 The Herger method of subset selection (Herger et al., 2018), as implemented here, uses quad-484 ratic integer programming to find the subset of models whose equally-weighted subset mean (EWSM) minimises a quadratic cost function. This cost function is chosen to measure the performance of the 485 486 EWSM in comparison to a given observational product. The two cost functions used here are: the 487 mean squared error (MSE) between the EWSM and the observational product (Herger et al. 2018, Eq.

1); and another which measures a combination of the MSE of the EWSM, the average MSE of each
subset member, and the average pairwise mean squared distance between subset members (Herger et
al. 2018, Eq. 2).

# 491 4.5 NARCliM2 CMIP6-RCMs: historical evaluation and climate change 492 projections

Performances of NARCliM2.0 versus NARCliM1.x RCMs in reproducing the recent Australian climate are evaluated by calculating the model biases (model outputs minus AGCD observations) for
mean maximum and minimum temperature and precipitation for 1990-2009. To enable comparison of
future projections between NARCliM1.0, NARCliM1.5 and NARCliM2.0 (where NARCliM1.0 modelled for 1990-2009, 2020-2039, and 2060-2079), all NARCliM ensemble projected changes are
shown as far future (2060–2079) minus present day (1990–2009).

#### 499 **4.6 Statistical significance**

500 When quantifying future climate change projections (compared to the historical period) and biases in 501 maximum and minimum temperature, the statistical significance is calculated for each grid cell using 502 t-tests ( $\alpha = 0.05$ ) assuming equal variance. The Mann–Whitney U test is used for precipitation given 503 its non-normality. For individual RCMs, grid cells showing statistically significant changes are stip-504 pled, otherwise they are shown in colour where change is statistically insignificant. Results on the

statistical significance of each ensemble mean are separated into three categories following Tebaldi et

- al. (2011): 1) statistically insignificant areas are shown in colour, denoting that less than 50% of
- 507 RCMs are significantly biased/different; 2) in areas of significant agreement (stippled), at least 50%
- 508 of RCMs are significantly biased/different and at least 70% of significant models in the CMIP6-
- 509 NARCliM2.0 RCM ensemble agree on the sign of the bias/difference. In such areas, many ensemble
- 510 members have the same bias sign which is an undesirable outcome; and 3) areas of significant disa-
- 511 greement, where at least 50% of RCMs are significantly biased/different and fewer than 70% of sig-
- 512 nificant models agree on the bias sign, are shown with diagonal hatching for the CMIP6-NARCliM2.0
- 513 historical evaluation and climate change signals.

## 514 5. RCM Physics test results

## 515 5.1 Phase I RCM performance summary

516 The spatial variation and magnitudes for Phase I RCM biases and RMSEs for annual mean maximum

- 517 and minimum temperature and precipitation are shown in Figures 4-5, respectively. Overall, RCMs
- are biased cold for maximum temperature (mean absolute bias for the ensemble mean = 1.18 K), and
- 519 warm-biased for minimum temperature (mean absolute bias = 1.31 K; Figure 4a-b). Maximum tem-
- 520 perature RMSE magnitudes are large over the elevated terrain of the southeast coast and over western
- 521 regions (Figure 5a). The simulation of precipitation shows biases of varying sign, with wet biases that
- 522 are strongest over eastern coastal regions (Figure 4c). Precipitation RMSEs are particularly large
- along the eastern coastline (>15 mm), and generally show an east-west gradient, i.e. progressively
- 524 decreasing further inland from the coast (Figure 5c).

#### 525 5.2 Comparing Phase II Physics Test RCM performances versus Phase I

#### 526 5.2.1 Climate Means

- 527 Overall, the RCM ensemble using New Goddard (NG) radiation has inferior performance to the corre-
- 528 sponding RCMs using RRTMG in terms of annual/seasonal mean maximum temperature biases,
- 529 RMSEs, and PSS (Table 7). In contrast, NG confers superior performance for annual/seasonal mean
- 530 minimum temperature for these statistics. RCMs using NG show reduced biases for annual mean and
- 531 spring-time precipitation, but larger errors for DJF and JJA (Table 7). RMSEs for annual and seasonal
- 532 precipitation are similarly variable.

- 533 Table 7. Climate means performance: phase II physics tests (i.e. N=12 set 1 changing only RRTMG to New
- 534 Goddard (NG) and N=12 set 2 changing only land surface model (LSM) from Noah-Unified to Noah-MP
- 535 (NMP) compared with the phase I physics test RCMs that were shortlisted for further testing (N=12).

			Bias			RMSE			PSS

536 Phase II RCMs using Noah-MP with RRTMG retained show improved performance in simu-

537 lating mean maximum and minimum temperature at annual timescales and most seasons relative to

538 corresponding Phase I RCMs using Noah-Unified (Table 7; Figure 4-5). For instance, the mean abso-

539 lute bias for annual mean maximum temperature is 0.58 K for the Noah-MP ensemble mean versus

540 1.18 K for the Noah-Unified ensemble. In particular, cold bias magnitudes for maximum temperature

s41 are considerably lower over eastern and southern regions for the RCMs using Noah-MP (Figure 4d).

542 RMSE magnitudes for maximum temperature are substantially reduced over the topographically com-

543 plex regions of the southeast, and southwest and central regions (Figure 5d).

544 Overall, the magnitude of warm biases for minimum temperature are broadly similar for

545 Phase I and Phase II RCMs (Figure 4b,c). Conversely, while RCMs in both Phases show large

546 RMSEs for minimum temperature over several eastern regions, RMSEs are smaller for the Noah-MP

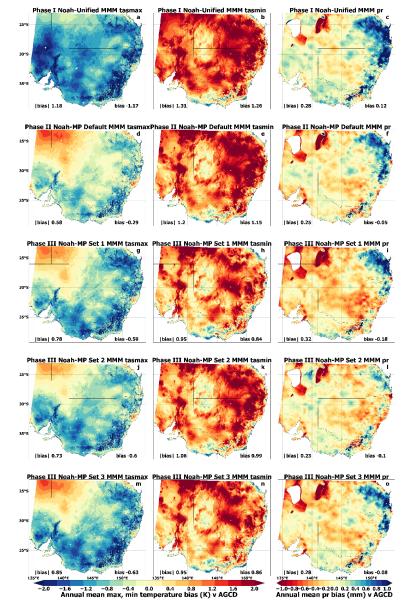

547 ensemble over some southern areas (Figure 5b,c).

- In contrast to the above results for the simulation of maximum temperature, overall, Phase II
  RCMs using Noah-MP show smaller performance improvements for the simulation of precipitation
  relative to the Phase I RCMs (Table 7). However, precipitation bias magnitudes are smaller for the
- 551 Noah-MP ensemble over specific regions, e.g. north-eastern coastal regions and the elevated terrain of
- 552 the south-east (Figure 4c,f).

553

#### 564 5.2.2. Climate Extremes

- 565 Climate extreme analysis assesses RCM representations of the hottest and the wettest day versus
- 566 AGCD. For both extremes and for RCM biases and RMSEs, Phase II RCMs using NG radiation
- showed inferior performance relative to phase I RCMs using RRTMG (Table 8). Conversely, Phase II
- 568 RCMs using Noah-MP show substantial reductions in bias for both the hottest and wettest days (Table
- 569 8). Phase II Noah-MP RCMs show a small increase in RMSE for the hottest day (Phase I bias=3.59
- 570 K; Phase II bias=3.74 K); however, RMSEs are smaller for the wettest day (i.e. Phase I RMSE=19.20
- 571 mm; Phase II RMSE=18.47 mm) (Table 8).
- 572 Table 8 Climate extremes performance: comparing phase I RCMs (N=12) with phase II RCMs (i.e.
- 573 12 RCMs changing radiation from RRTMG to New Goddard (NG) and 12 RCMs changing land sur-
- 574 face model (LSM) from Noah-Unified to Noah-MP; NMP).

# 5.3 Phase III RCM performance summary and shortlisting N=7 RCMs for 576 ERA5-NARCliM2.0 evaluation simulations

577 Overall, RCM biases for mean maximum temperature do not show marked improvements once the

578 dynamic vegetation cover and surface runoff options are activated for Noah-MP (Figure 4 g,j,m) rela-

579 tive to RCMs using Noah-MP with default settings (Figure 4d). However, specifically for the RCM

- 580 ensemble with dynamic vegetation cover activated for Noah-MP, RMSE magnitudes for maximum
- temperature are lower over some eastern coastal regions (Figure 5g).
- 582 The simulation of mean minimum temperature shows clear performance improvements for
- 583 Phase III RCMs using options activated for Noah-MP, relative to RCMs using Noah-MP defaults.
- 584 Overall, both biases and RMSEs for minimum temperature are reduced in magnitude for RCMs using
- 585 the either or both of dynamic vegetation cover and runoff/groundwater options activated for Noah-

586

MP, relative to the default parameters (Figure 4-5). These performance improvements are largest over 587 eastern and southern regions. 588 There are no substantial overall performance improvements in the simulation of precipitation 589 for Phase III RCMs relative to Phase II RCMs (Figures 4-5 f,i,l,o). However, using Noah-MP with 590 specific LSM options remains favourable to using RCMs with Noah-Unified, albeit the performance gains are generally small, except for some coastal regions and especially the north-east. 591 592 All 78 RCMs in the complete RCM physics test ensemble are ranked for performance as described in sect. 4.2. Once the poor-performing RCMs are excluded, there are 20 RCMs remaining 593 594 (Table 9; Figures 6-8). In Table 9, we see that 16 Noah-MP-based RCMs from Phase II and Phase III 595 comprise this set of 20 RCMs, with 3 of the 20 RCMs using Noah-Unified, and 1 using CLM4.0. For 596 maximum temperature, some shortlisted RCMs show large RMSEs over north-western and inland 597 areas (e.g. Figure 6 d-f) that are of similar magnitude to those of the ensemble means of Phase I-III 598 RCMs (Figure 5). Conversely, several shortlisted RCMs show very low RMSEs for maximum tem-599 perature across eastern and southern regions, especially along the eastern coast (Figure 6, e.g. RCMs 600 in panels d,l,n,o,q). For minimum temperature, a subset of the twenty shortlisted RCMs show substan-601 tially reduced RMSEs over many regions relative to the Phase I-III ensemble means (Figure 7, e.g. 602 RCMs in panels: b,h,i). Additionally, several shortlisted RCMs show reduced RMSEs for precipita-603 tion over the eastern coast and north-east (Figure 8, e.g. RCMs in panels: c, l, m, n, o) relative to the 604 Phase I-III RCM ensemble means in Figure 5c,f,i,l,o. 605 These 20 RCMs are assessed for statistical independence and 7 RCMs from this RCM set are 606 shortlisted for the ERA5-forced RCM simulations considering both their performance and independ-607 ence scores (Table 9). These 7 shortlisted RCMs are listed in **bold** in Table 9 and are identified as R1-608 R7 in the ERA5-forced evaluation simulations (Table 9; final column). RCMs are shortlisted from the set of 20 if they rank highly for both performance and independence. For instance, RCM 609 050801040404\_set\_3 (top row, Table 9) is top-ranked for performance, however, its independence 610 611 scores/ranks are low, hence it is not shortlisted. It is important to note that, while a general perfor-612 mance gain is observed in the physics testing when using Noah-MP, there are some specific RCM 613 configurations using Noah-Unified that perform well in simulating the Australian climate. For instance, the RCM 010602050502 (row 7; Table 9; 'R1') uses Noah-Unified and performs well overall 614 615 (its overall performance rank=7), and especially for the simulation of maximum temperature (Figure 6a). It is also the only RCM in this set of 20 RCMs to use YSU for PBL. Importantly, this RCM is 616 617 highly ranked for statistical independence, hence, this RCM is shortlisted for the N=7 set.

# 631 6. CORDEX-CMIP6 NARCliM2.0 historical evaluation

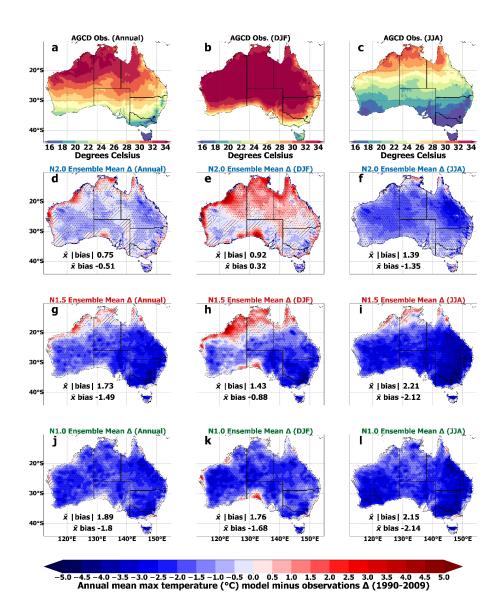

#### 632 6.1 Maximum temperature

629

633 NARCliM2.0 RCMs simulate maximum temperature more accurately than NARCliM1.x, with wide-634 spread, statistically significant reductions in cold biases (Figure 9). These reductions in bias apply for 635 all timescales but are largest for the annual mean, i.e. the area-averaged mean absolute bias is 0.75°C 636 for the NARCliM2.0 ensemble, 1.73°C for NARCliM1.5, and 1.89°C for NARCliM1.0 (Figure 637 9d,g,j). Notably, annual mean maximum temperature bias magnitudes are very small, i.e. around 638 <0.5°C, over south-west WA, southern coastal regions, and several eastern regions. This may be important from a climate change adaptation and mitigation perspective as these regions are heavily pop-639 640 ulated and economically significant. NARCliM2.0 retains warm biases of similar magnitude to NAR-641 CliM1.5 along the north-west coast of Australia (Figure 9d,g). Moreover, these warm biases cover 642 additional areas for NARCliM2.0, especially during DJF (Figure 9e,h). A wide range of bias signs are evident for the individual NARCliM2.0 ensemble members (Figures S4-S6). The R5 RCM is general-643 644 ly warmer than R3, e.g. (Figure S4c,d). Considering the forcing GCM data, overall, ensemble means 645 for the CMIP6 and CMIP5 GCMs generally show similar patterns and magnitudes of cold bias for 646 maximum temperature (Supporting Information S7).

647

648 Figure 9. Annual, DJF and JJA mean near-surface atmospheric maximum temperature biases for NARCliM2.0, 649 1.5 and 1.0 historical ensemble means with respect to Australian Gridded Climate Data (AGCD) observations 650 for 1990-2009. Stippled areas indicate locations where an RCM shows statistically significant bias (P<0.05). 651 Significance stippling for the ensemble mean bias follows Tebaldi et al. (2011) and is applied separately to each 652 RCM ensemble. Statistically insignificant areas are shown in colour, denoting that less than half of the models 653 are significantly biased. In significant agreeing areas (stippled), at least half of RCMs are significantly biased, and at least 70% of significant RCMs in each ensemble agree on the direction of the bias. Significant disagree-654 655 ing areas are shown in hatching, which are where at least half of the models are significantly biased and less 656 than 70% of significant models in each ensemble agree on the bias direction - see main text for additional detail 657 on the stippling regime.

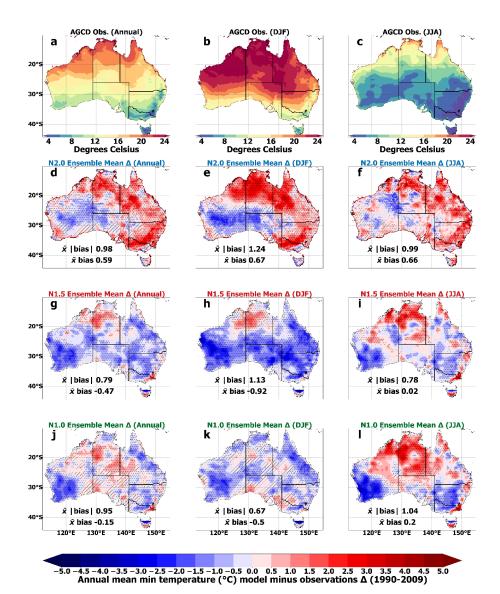

# 658 6.2 Minimum temperature

659	The simulation of mean minimum temperature by NARCliM2.0 is generally warm biased at all time-
660	scales (Figure 10). Its bias magnitudes over many regions are larger versus NARCliM1.5, e.g. annual
661	mean area-averaged absolute biases are 0.98°C and 0.79°C for NARCliM2.0 and NARCliM1.5, re-
662	spectively (Figure 10 d,g). However, there are exceptions to this result over specific regions, for ex-
663	ample, parts of south-west western Australia show annual mean bias magnitudes of <1°C for NAR-
664	CliM2.0, but these areas show biases below -2°C for NARCliM1.x (Figure 10d,g,j). Most individual
665	RCMs comprising the NARCliM2.0 ensemble show stronger warm biases than their NARCliM1.5
666	peers at both annual and seasonal timescales (Figures S8-S10). The ACCESS-ESM-1-5-forced NAR-
667	CliM2.0 RCMs are considerably more warm-biased than the other NARCliM2.0 RCMs, with average
668	absolute biases of 1.74°C and 1.9°C; Fig. S8c-d).
669	Many of the CMIP6 GCMs used to force the NARCliM2.0 RCMs are warmer than the CMIP5
670	GCMs used to force NARCliM1.5, such that the ensemble mean bias of the former is 1.9°C versus
671	1.11°C (Figure S11). In particular, ACCESS-ESM-1-5 and MPI-ESM1-2-HR are substantially more
672	warm-biased relative to all other selected GCMs, with mean absolute biases of 2.2°C and 3.47°C, re-
673	spectively (Figure S11). This suggests that NARCliM2.0's warm biases for mean minimum tempera-
674	ture are at least partially inherited from the driving data. However, whilst the ACCESS-ESM-1-5-
675	forced NARCliM2.0 RCMs are much warmer than their counterparts (i.e. 1.74°C and 1.9°C), this
676	does not apply to the MPI-ESM1-2-HR-forced RCMs, which have biases of only 1.01°C and 1.09°C.
677	Hence, factors additional to the driving data, such as changes in RCM parameterisations between
678	NARCliM generations and other model design changes likely contribute to the warmer biases ob-
679	served for NARCliM2.0.

680

681 Figure 10. As per Figure 9 but for mean minimum temperature.

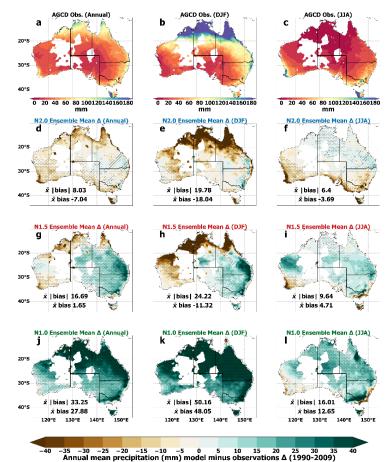

#### 682 **6.3 Precipitation**

683 The NARCliM2.0 ensemble shows small dry biases for mean precipitation over most regions, except for some areas mainly in the east of the country which show slight wet biases (Figure 11d-f). This 684 contrasts with stronger, statistically significant wet biases of NARCliM1.5 (Figure 11g-i) and the even 685 stronger wet biases of NARCliM1.0 (Figure 11j-l). Area-averaged bias magnitudes are considerably 686 smaller for NARCliM2.0 relative to NARCliM1.x, especially for the annual mean, i.e. 8.03 mm ver-687 688

689 over eastern regions, often being <5 mm. NARCliM2.0 retains the strong summertime dry biases for 690 precipitation over northern Australia that are evident for NARCliM1.5 (Figure 11e,h), noting that this 691 region also shows strong warm biases for maximum temperature (Figure 9). 692 The individual RCMs comprising NARCliM2.0 show a range of results for annual and sea-693 sonal mean precipitation biases (Fig S12-S14). Notably, three of the ten NARCliM2.0 RCMs have substantially larger bias magnitudes than their peers at annual and summer timescales, i.e. both MPI-694 695 ESM1-2-HR-R3 and R5 (absolute biases are 15.53 mm and 22.45 mm for annual mean precipitation, 696 Figure S12g-h) and EC-Earth3-Veg-R5 (Figure S12f; 18.59 mm). Despite EC-Earth3-Veg-R5 being 697 strongly dry-biased, EC-Earth3-Veg-R3 simulates precipitation more accurately i.e. its mean absolute 698 bias=9.53 mm (Figure S12e). Analogously to NARCliM2.0's performances for temperature, R5 is 699 drier than R3. Comparing the ensemble means of the driving GCMs, the CMPI6 GCMs are marginal-700 ly more accurate in simulating annual mean precipitation than the CMIP5 GCMs (Figure S15). Whilst 701 the CMIP6 ensemble produces small biases over inland regions, its biases are larger along the east 702 coast.

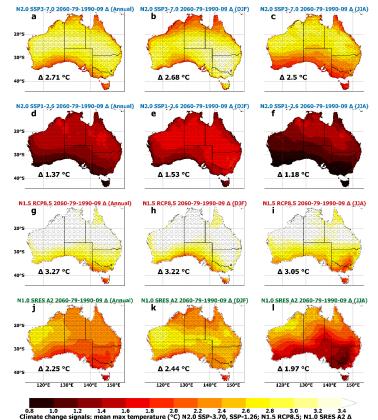

703 Annual mean precipitation (mm) model minus
 704 Figure 11. As per Figure 9 but for mean precipitation (precip.).

## 705 7. CORDEX-CMIP6 NARCliM2.0 climate change projections

- 706 Dependent on location, the largest maximum temperature projected increases for NARCliM2.0 under
- 507 SSP3-7.0 are over ~3°C, and over ~1.5°C under SSP1-2.6 (Figure 12a,d). SSP3-7.0-NARCliM2.0
- ros shows faster warming over inland than coastal regions, with greater warming across a horizontal band
- 709 of the continent during annual and summer timescales (Figure 12a-b). This contrasts with NAR-
- 710 CliM1.5 which shows a north-south warming gradient at annual and seasonal timescales, with its fast-
- 711 est warming rate over northern regions, and NARCliM1.0 which projects fastest warming over the
- 712 west (Figure 12). For NARCliM2.0, the tropical north warms faster during the winter dry season than
- 713 during the summer wet season under SSP3-7.0, but this is not the case for SSP1-2.6 (Figure 12b-c; e-
- f). NARCliM2.0 simulations under SSP3-7.0 show less warming than NARCliM1.5-RCP8.5, but
- 715 warmer futures than for NARCliM1.0-SRES A2, with differences in the underlying driving GCMs
- and GHG scenarios likely contributing to these variations in warming. As per NARCliM1.x, all
- 717 NARCliM2.0 maximum temperature projections are significant-agreeing with all RCMs projecting
- 718 statistically significant temperature increases.

719

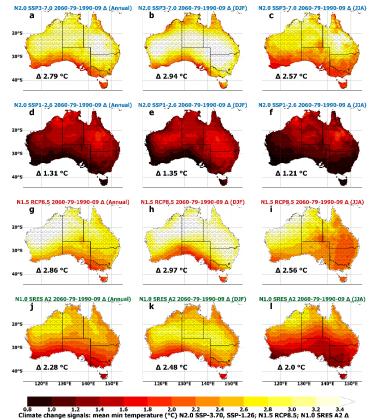

**Figure 12.** Ensemble mean climate change projections (far future minus present-day) for annual, DJF and JJA

721 mean maximum temperatures with significance stippling as per Figure 9.

- 722 Projected increases in annual mean minimum temperature for NARCliM2.0 exceed 3°C over
- 723 some regions for SSP3-7.0, and 1.6°C for SSP1-2.6 (Figure 13). Under both GHG scenarios, at annual
- 724 and winter timescales warming is fastest over north-east Australia. Conversely, NARCliM1.x mini-
- 725 mum temperature future increases are generally largest over northwest or northern Australia, though
- 726 the summertime projection for NARCliM1.0 is an exception (Figure 13k). As for maximum tempera-
- 727 ture projections, all RCMs for all NARCliM generations project statistically significant increases.

728

729 Figure 13. Ensemble mean climate change projections (far future minus present-day) for annual, DJF and JJA

730 mean minimum temperatures with significance stippling as per Figure 9.

731NARCliM2.0 SSP3-7.0 projects a dry future over most of Australia, except for wetter futures

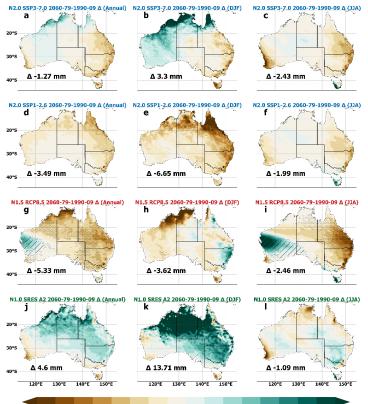

over northern and western regions, which are largest in magnitude in summer (Figure 14a-b). In con-

trast, overall, NARCliM2.0 SSP1-2.6 projects dry changes across most of Australia, with the strongest

- 734 drying over northern Australia during summer (Figure 14e). Similarities between NARCliM2.0 pro-
- 735 jections for the low and high GHG SSPs include faster drying over the eastern coastline at all time-
- rd scales, especially during summer. The wetter futures projected by RCMs downscaling SSP3-7.0-
- 737 GCMs relative to SSP1-2.6 may be partially inherited from the driving CMIP6 GCMs, because over-
- all, SSP3-7.0 GCMs show wetter futures than corresponding SSP1-2.6 GCMs (Fig. S16).

739

-20.0 -17.5 -15.0 -12.5 -10.0 -7.5 -5.0 -2.5 0.0 2.5 5.0 7.5 10.0 12.5 15.0 17.5 20.0 Climate change signals: mean precipitation (mm) N2.0 SSP-3.70, SSP-1.26; N1.5 RCP8.5; N1.0 SRES A2 Δ

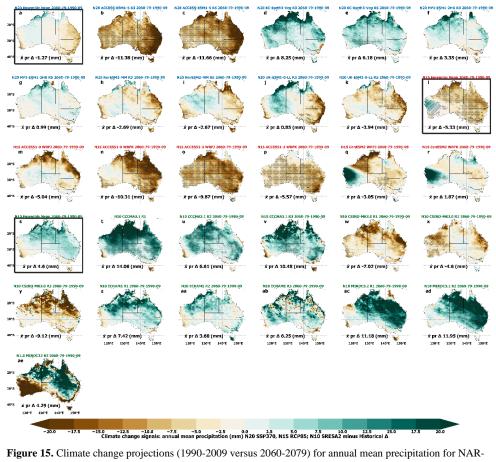

Figure 14. Ensemble mean climate change projections (far future minus present-day) for annual, DJF and JJA
mean precipitation with significance stippling as per Figure 9.

742 Considering mean precipitation projections for individual NARCliM2.0 RCMs, in some cases, 743 R3 and R5 RCMs produce similar results when downscaling the same GCM. For instance, ACCESS-744 ESM-1-5 forced R3 and R5 both show statistically significant projected decreases in annual mean 745 precipitation across Australia (Figure 15b-c). In contrast, while UK-ESM1-0-LL R3-R5 both show 746 projected decreases in annual mean precipitation over eastern Australia, R3 shows precipitation in-747 creases that are substantially more widespread over western and northern regions relative to R5 (Fig-748 ure 15j-k). Overall, the NARCliM2.0 ensemble members show a variety of climate change signals for 749 precipitation (Figure 15) and temperature (not shown), reflecting the range within the larger CMIP6 750 ensemble (Di Virgilio et al. 2022). 751 There are some key differences between the mean precipitation projections of NARCliM2.0 rela-752 tive to those of previous NARCliM generations. For instance, NARCliM1.5 shows stronger reduc-753 tions in future precipitation over northern and eastern regions at annual and winter timescales (Figure 754 14), and these changes are statistically significant over many regions, whereas there are only small regions of significant changes for NARCliM2.0. Additionally, NARCliM2.0 projects marked precipi-755

- tation decreases along the south-east coast during summer, while NARCliM1.5 shows the opposite
- 757 result (Figure 14). NARCliM1.0 generally projects wet futures across larger portions of Australia,
- 758 especially at annual and summer timescales.

761 CliM ensemble mean climate change signals (a,l,s) and for individual ensemble members. Significance stippling762 as per Figure 9.

# 763 8. Discussion and Summary

- 764 NARCliM regional climate models produce robust climate projections at spatial scales suitable for
- 765 local-scale climate change analysis and impact decision-making. The third and latest generation of
- 766 these regional climate models, NARCliM2.0, encompasses several model design advancements over
- 767 its predecessors.

759 760

# 768 8.1 NARCliM2.0 RCM physics testing

769	A key aim of this paper is to describe how NARCliM2.0 differs from its predecessors and explain the
770	rationale for these design decisions. In addition to RCM design choices including increased resolu-
771	tion, and incorporation of convection-permitting modelling and urban physics, a major change for
772	NARCliM2.0 relative to its predecessors is to use new WRF RCM configurations which are selected
773	via a large suite of physics tests. RCM performance evaluations for the NARCliM2.0 RCM physics
774	testing focused on the 4 km resolution convection-permitting domain which does not use a cumulus
775	physics parameterisation. Notably, the 7 'candidate' shortlisted RCMs from the N=78 physics test
776	ensemble used three different cumulus parameterisations for their outer domains, with 4 RCMs using
777	BMJ, 2 RCMs using Tiedtke, and 1 using Kain-Fritsch. This indicates that differences in the outer
778	domain boundary conditions have key influences on the RCM performances in the convection-
779	permitting domain.
780	The use of the Noah-MP LSM in the NARCliM2.0 RCM physics tests conferred overall RCM
781	skill improvements relative to the test Phase I RCMs using the Noah-Unified LSM, especially in
782	terms of the simulation of temperature. Although using Noah-MP also improved the simulation of
783	precipitation in some respects, these improvements were smaller relative to the gains for temperature,
784	and improvements were mainly located over coastal regions. The developers of Noah-MP suggest that
785	some limitations in the Noah-Unified LSM have been modified to better represent several parameters.
786	These include surface layer radiation balances, snow depth, soil moisture and heat fluxes, leaf area-
787	rainfall interaction, vegetation and canopy temperature distinction, drainage of soil, and runoff.
788	In the NARCliM2.0 physics testing, improvements in RCM skill were evident for Noah-MP
789	with default settings. Activating specific parameterisations for this LSM (i.e. dynamic vegetation cov-
790	er and surface runoff-simple groundwater) delivered comparatively smaller gains in RCM perfor-
791	mances. Some previous studies have found no overall benefit of using Noah-MP with default settings.
792	For instance, Imran et al. (2018) conducted an evaluation of WRF coupled with a variety of LSMs
793	including Noah-MP using its default settings. Their focus was on simulating short-duration (~3-day)
794	heatwaves in Melbourne, Australia. They observed larger temperature biases using Noah-MP relative
795	to RCMs using Noah-Unified and CLM4.0. However, their focus on specific heatwave events of short
796	duration over one urban area was not intended as a comprehensive evaluation of Noah-MP's perfor-
797	mance using default settings over longer timescales. It is also important to consider that several phys-
798	ics schemes used by these authors differed to those used in the NARCliM2.0 physics testing, i.e. they
799	used: PBL=MYJ; microphysics=Thompson; cumulus=Grell3D; radiation=RRTMG/RRTMG. The
800	only similarities between these settings and those of the NARCliM2.0 physics testing are the use of
801	Thompson microphysics and RRTMG. WRF and Noah-MP versions also differed, i.e. Imran et al.
802	used WRF3.6.1 and a Noah-MP version prior to 3.7, whereas NARCliM2.0 uses WRF4.1.2 and No-
803	ah-MP version 4.1.

804	In an assessment of the performances of several WRF-LSMs for Sub-Saharan Africa, Glotfelty et
805	al. (2021) noted deficiencies in the simulation of land use and land cover change (LULCC) parame-
806	ters such as surface albedo by Noah-MP. Despite these deficiencies, the spatial patterns and magni-
807	tudes of temperature and precipitation were well-represented by Noah-MP. However, the land surface
808	parameter errors impacted the magnitude and sign of LULCC-induced changes in temperature and
809	precipitation. These deficiencies were linked to substantial underestimations of surface albedo in arid
810	areas due to inaccurate soil albedo treatments by Noah-MP. Moreover, errors in Noah-MP's LAI pro-
811	files may occur because it was developed principally for application in Northern Hemisphere mid-
812	latitudes. It is possible that modifying/tuning Noah-MP to specific aspects of the Australian context
813	would yield performance benefits for follow-up dynamical downscaling. Overall, these authors con-
814	cluded that "Noah-MP is least flawed of the [WRF] default LSMs". Additionally, there are also sever-
815	al studies that have reported benefits of using Noah-MP with default parameters relative to other
816	LSMs e.g. Chen et al. (2014b), Chen et al. (2014a) and Salamanca et al. (2018).
817	The NARCliM2.0 physics testing found that the optimal LSM configuration for simulation of
818	minimum temperature used Noah-MP with dynamic vegetation cover activated, even though the per-
819	formance gain relative to Noah-MP with default settings was small. Constantinidou et al. (2020) ran
820	WRF coupled with four LSMs (Noah-Unified, Noah-MP, CLM and, Rapid Update Cycle) over Mid-
821	dle East North Africa CORDEX domain. Their study compared the performance of Noah-MP with
822	dynamic vegetation cover turned on and off. They showed that air and land temperatures were best
823	simulated using Noah-MP with dynamic vegetation cover activated.
824	Overall, Noah-MP performed well in the NARCliM2.0 physics tests, conferring some clear ad-
825	vantages over RCMs using Noah-Unified. However, given the nature of its development and perfor-
826	mance characteristics, it may be more suited to application over the temperate regions of Australia
827	rather than the semi-arid interior.
828	In terms of PBL parameterisations, by the completion of Phase I physics testing, only 3 of 12
829	RCMs shortlisted for further testing use the YSU scheme. By the completion of Phase II testing, all
830	remaining RCMs using YSU are discarded, with only RCMs using PBL schemes other than YSU re-
831	maining (i.e. ACM2 and MYNN2). YSU PBL is a first-order closure scheme that expresses turbulent
832	mixing via mean variables rather than prognostic variables (Hong et al., 2006). It is classed as a 'non-
833	local' scheme because it estimates turbulent mixing by small-scale eddies as well as representing
834	transport caused by convective large eddies. Two previous studies evaluating convection permitting
835	WRF simulations using different parameterisations that included YSU for the PBL scheme found that,
836	relative to other PBL schemes, YSU produced the highest bias for simulated precipitation (Huang et
837	al., 2023; Nuryanto et al., 2019). However, these studies focused on different regions globally, and
838	used various experimental setups that are not directly comparable to those used here. Hence, a sepa-
839	rate study investigating sensitivities of the NARCliM2.0 RCMs to the different PBL schemes is cur-
840	rently underway.

# 841 8.2 CMIP6-NARCliM2.0: historical evaluation and climate change 842 projections

843 We characterised the improvements conferred by NARCliM2.0 over its predecessors in simulating the 844 present-day Australian climate. NARCliM2.0 simulates mean maximum temperature and precipitation more accurately than NARCliM1.x. Specifically, NARCliM1.x has strong maximum temperature cold 845 846 biases which are in keeping with other downscaling projects of the CMIP3-CMIP5 eras, e.g. (Andrys 847 et al., 2016; Evans et al., 2020b), but these are substantially reduced in NARCliM2.0. A contributing 848 cause of CMIP5-forced RCM cold biases of maximum temperature is their overestimation of precipi-849 tation (Evans et al., 2020). This relationship was also noted in ERA-Interim forced RCMs of this 850 modelling era (Di Virgilio et al. 2019). In NARCliM2.0, the widespread wet biases that characterise 851 the NARCliM1.x RCMs are greatly reduced in magnitude. NARCliM2.0 produces smaller wet biases 852 over eastern Australia, and smaller dry biases elsewhere, except for Australia's tropical north. This 853 marked reduction in wet bias magnitudes is a plausible contributing cause for the reduction in maxi-854 mum temperature cold bias for the NARCliM2.0 RCMs. The CMIP6 and CMIP5 GCMs used to drive 855 NARCliM2.0 and 1.5 RCMs generally show similar magnitudes of maximum temperature cold bias. 856 This suggests that the underlying nature of the CMIP6 driving data is not a principal factor underlying 857 the observed improvements for NARCliM2.0's simulation of maximum temperature. In fact, the 858 RCMs appear to have a substantial influence on the reduced maximum temperature biases. 859 That NARCliM2.0 underestimates precipitation over tropical northern Australia during the 860 wet season (summer) to a similar degree of magnitude to the NARCliM1.5 RCMs indicates that the 861 newer models still struggle to accurately capture the strength of the Australian monsoon. However, 862 whereas NARCliM1.x strongly overestimates precipitation over south-eastern and southern Australia, wet biases over these regions are reduced for NARCliM2.0 RCMs. This indicates that the newer mod-863 els may confer an improved simulation of broad-scale processes associated with synoptic-scale sys-864 865 tems interacting with the extratropical storm track over Australia (Grose et al., 2019). 866 NARCliM2.0 RCMs overestimate minimum temperatures across Australia, and these biases 867 are larger relative to NARCliM1.5 but comparable to those of NARCliM1.0. The CMIP6 GCMs used 868 to force NARCliM2.0 show substantially stronger warm biases for minimum temperature than the 869 CMIP5 GCMs used for NARCliM1.5. This suggests that the increased warm bias for minimum tem-870 perature in NARCliM2.0-RCMs is partially inherited from the driving GCMs. However, as noted 871 above, the Noah-MP LSM simulation of factors such as LAI and other aspects of vegetation as well as 872 surface albedo in arid areas may contribute to the biases shown by the NARCliM2.0 RCMs. Moreo-873 ver, the NARCliM2.0 ensemble mean reduces the overall minimum temperature bias of the CMIP6 874 GCM ensemble by almost half, attesting to the added value conferred by the NARCliM2.0 RCMs 875 with respect to near-surface temperature variables.

876	In terms of NARCliM2.0 future climate projections, major changes between NARCliM genera-
877	tions such as differences in GHG scenarios mean that NARCliM2.0 projected temperature changes
878	differ in some respects to those of its predecessors. Overall, as is expected, projected warming is less
879	intense in NARCliM2.0 under SSP3-7.0 than for NARCliM1.5 under RCP8.5. Other differences in
880	the projections between NARCliM generations require further investigation in order to explain, such
881	as NARCliM1.5's latitudinal warming gradient for maximum temperature that contrasts with NAR-
882	CliM2.0's band of faster warming over central Australia relative to northern and southern regions.
883	Irrespective of these differences, all three NARCliM ensembles show statistically significant-agreeing
884	results for warming projections.
885	Precipitation projections for the different NARCliM generations show some key similarities,
886	such as reductions in mean annual precipitation over eastern Australia for NARCliM2.0 and NAR-
887	CliM1.5, though a difference is that these are statistically significant only for NARCliM1.5. The
888	NARCliM2.0-SSP3-7.0 and SSP1-2.6 ensembles differ in that the former generally projects wet
889	changes over northern and western Australia, whereas the latter is generally dry, results that appear
890	partially traceable to the underlying driving CMIP6-SSP data. Other notable differences are that some
891	NARCliM2.0 RCMs produce very similar precipitation projections for certain GCM-RCM combina-
892	tions, such as for ACCESS-ESM-1-5 forced R3 versus R5 under SSP3-7.0 (i.e. widespread dry pro-
893	jections for both RCMs). Conversely, in other instances, there are marked divergences between the R3
894	versus R5 precipitation projections when forced with the same GCM, for instance, UK-ESM-1-0-LL
895	under SSP3-7.0 where R3 projects stronger precipitation increases that are more geographically wide-
896	spread relative to R5. This raises the question of varying sources of uncertainty in the climate projec-
897	tions, i.e. to what extent these are attributable to GCMs versus RCMs, as well as other factors.
898	In summary, the CORDEX-CMIP6 NARCliM2.0 regional climate projections are a 10-member
899	ensemble comprising two configurations of the WRF RCM dynamically downscaling five GCMs un-
900	der three SSPs at 20 km resolution over CORDEX-Australasia and at 4 km convection-permitting
901	resolution over south-east Australia. The main aims of this manuscript are to describe the new
902	CORDEX-CMIP6 NARCliM2.0 RCM ensemble, explaining how and why its design choices were
903	made including the model test and evaluation approaches underlying these design decisions; and char-
904	acterise improvements in model skill in simulating the recent Australian climate relative to previous
905	generations of NARCliM, as well as differences in future climate projections. In addition to several
906	high-level model design changes, e.g. increased spatial resolution, a large (N=78) RCM-physics test
907	suite is evaluated to select two new WRF RCM configurations for CMIP6-forced NARCliM2.0 cli-
908	mate projections. Due to resource constraints and the aim to test a large number of RCM physics pa-
909	rameterisations, the NARCliM2.0 physics tests are performed for a single year. This is one reason
910	why the final selection of two production-grade RCMs for the CMIP6-NARCliM2.0 runs is based on
911	the CORDEX ERA5-forced 42-year evaluation simulations. The NARCliM2.0 physics tests identified
912	RCM configurations that generally performed well in simulating the recent Australian climate over

- 913 southeast Australia. A key finding was that WRF RCMs using the Noah-MP LSM generally out-
- 914 performed RCMs using other WRF LSMs in representing regional climate. Despite the performance
- 915 gains evident for RCMs using Noah-MP, RCM skill was superior over the temperate/coastal regions
- 916 of southeast Australia, relative to the semi-arid interior. These performance characteristics might be
- 917 linked to Noah-MP's development being focused on Northern Hemisphere mid-latitudes, including
- 918 assumptions such as accounting for differences in seasonality in the Northern versus Southern Hemi-
- 919 spheres by shifting the Northern Hemisphere LAI profiles by 6 months. For the southeast Australian
- 920 context, noting its distinctive coastal dry-sclerophyll and expansive inland grassland biomes, such
- 921 assumptions might lead to discontinuities in quantities such as LAI. Hence, future investigation into
- 922 processes such as land-surface coupling in NARCliM2.0 RCMs is warranted.
- 923 Overall, the CMIP6-NARCliM2.0 ensemble produces a good representation of recent mean cli-
- 924 mate that in several key respects improves upon the model skill of earlier NARCliM generations. This
- study provides a foundation for more detailed investigations of the model biases and future climate
- 926 changes described here, including process-focused studies exploring their mechanisms. CORDEX-
- 927 CMIP6 NARCliM2.0 RCM data provide valuable resources to investigate projected climate changes,
- 928 their impacts on societies and natural systems, and potential climate change mitigation and adaptation
- 929 actions for the CORDEX-Australasia region.

#### 930 9. Code Availability

- 931 The Weather Research and Forecasting (WRF) version 4.1.2 used in this study is freely available
- 932 from: https://github.com/coecms/WRF/tree/V4.1.2. A static copy of all scripts used for this study can
- 933 be found at: <u>https://bitbucket.org/oehcas/narclim2-</u>
- 934 <u>0\_design\_and\_evaluation\_2024\_support\_materials/src/main/</u>

#### 935 **10. Data Availability**

- 936 Data for the NARCliM2.0 CMIP6-forced R3 and R5 RCMs are being made available via National
- 937 Computing Infrastructure (NCI). WRF namelist settings for the NARCliM2.0 CMIP6-forced R3 and
- 938 R5 RCMs are shown in Supplementary Material Figure S1 and are also available at:
- 939 https://bitbucket.org/oehcas/narclim2-0 design and evaluation 2024 support materials/src/main/.
- 940 Data NARCliM1.5 RCMs are available via the <u>New South Wales Climate Data Portal</u> and <u>CORDEX-</u>
- 941 DKRZ. Data for NARCliM1.0 RCMs are available via the New South Wales Climate Data Portal.
- 942 CMIP6 GCM data are available via the Earth System Grid Federation.

# 943 **11. Author Contribution**

- 944 GDV and JPE designed the models and the simulations. FJ, ET, and CT setup the models and
- 945 conducted the model simulations with contributions from JPE, JK, JA, DC, CR, SW, YL, MER, RG
- and JL. GDV prepared the manuscript with contributions from all co-authors.

# 947 12. Competing Interests

- 948 The authors declare that they have no conflict of interest, noting that JK is a Topic Editor of
- 949 Geoscientific Model Development.

#### 950 **13. Funding**

- 951 This research was supported by the New South Wales Department of Climate Change, Energy, the
- 952 Environment and Water as part of the NARCliM2.0 dynamical downscaling project contributing to
- 953 CORDEX Australasia. Funding was provided by the NSW Climate Change Fund for NSW and
- 954 Australia Regional Climate Modelling (NARCliM) Project. This research was undertaken with the
- 955 assistance of resources and services from the National Computational Infrastructure (NCI), which is
- 956 supported by the Australian Government.
